Some of the results shown at the New Gallery are very good, others distinctly disappointing, and I think all who have seen them will agree that the lighting is far from good. The slides projected by the lantern seem to do justice to this new process, more than the transparencies in the balcony; but, of course, the whole process is at present a novelty to most workers, and no doubt admits of improvement.

Meanwhile, the question of colour permanency may be worth a little discussion, should you consent to allow it to take place in your columns, which have recently devoted space to the question of colour photography.—I am, gentlemen, yours faithfully,

Croydon.

J. H. BALDOCK.

## Answers to Correspondents.

- \*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \*\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \*\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- H. Owen, The Quarry, Stourbridge, Worcestershire. *Photograph from a Black and White Drawing of the American Clipper Ship "Flying Cloud"*
- Miss E. Dundas, 7, Irving Mansions, Queen's Club Gardens, W. *Photograph of the Rev. F. E. Murphy*
- A. E. T. Jordan, 24, Lavender Hill, London, S.W. *Photograph of the Interior of St. Philip's Church, Queen's Road, Battersea.*
- W. Harrison, The Studio, Skipton Road, Barnoldswick. *Photograph of the Barnoldswick Prize Brass Band and Band Officials.*
- J. Hodgson, 158, South Parade, Cleckheaton, Yorks. *Two Photographs of the Conductor's Funeral, Pynest Tram Smash.*
- Miss M. Wright, 75, Albert Road, Middlesbrough. *Photograph (Flashlight) of the Middlesbrough Amateur Operatic Society in "The Mikado."*

COOPER-HEWITT LAMPS.—Could you obtain for me the address of the makers or agents of the Cooper-Hewitt mercury vapour electric lamp, as used by "Daily Mirror" to photograph French Municipal councillors at dinner?—T. J. BENNETT.

The lamps are made by the Cooper-Hewitt Co., of New York, and sold in this country by the Westinghouse Co., Norfolk Street, Strand, W.C., who are agents of the manufacturers.

A READER.—We believe quick production, such as you allude to, has been done several times. If you could cite the issue containing our report we could perhaps give you particulars.

COPYRIGHT.—Could you advise me what to do in this case? I to Halifax and took a photograph of the funeral of the conductor who was killed in the tram accident. A local stationer from Halifax called on me the same day and wished to buy a print for reproduction in penny cards. I refused to him one, and also told him I was getting a print ready to right the same. I supplied a shop in Halifax with 40 postcards. The stationer above referred to bought six of man, and the same night was offering penny ones for sale of photographic postcards. What can I do? Can I stop him and have I good case for claiming damages? He was told was doing wrong, but he says he has bought the card and a right to do what he likes with it. I may say I do a large in photographic postcards, and this copying business is becoming rather common, and I wish to stop it, and I should like to an example of some one.—J. HODGSON.

Your remedy is quite simple. Register the copyright of subject before issuing it. In the present instance you could do anything in respect of copies issued before your registration of the copyright.

W. E. DAW.—1. A thin coat of pure asphalt varnish would probably remedy matters. 2. The second of the cameras is the one I should prefer, particularly the higher priced patterns. It is essentially a question of cost.

J. A. JAMES.—A lamp in which a powder can be burnt in a space will be better than any other form of light as regards smoke. We expect the audience will have to put up with smoke, however. Your best course is to use a good powder, as the Agfa, and lay a train of it in a long narrow tray. It is impossible to say what your exposure will be; it depends largely on the colour of the walls.

F. C. T.—A strong pure paste, such as Vanguard Fixit, will answer quite well, as will also a thick shellac solution. There is no means of applying it to the back only except by exercising care.

S. B. T.—The sample you send is an ordinary lithographic transfer. Litho-transfer paper is bought, sensitised with bichromate then printed underneath a negative, which has previously been made to the correct size from the drawing it is required to reproduce. It is then rolled up and developed, and is then ready for the lithographic printer. Nothing can be more simple. This looks a somewhat unusual kind of lithographic transfer paper, or has had an unusual amount of rubbing, or hot water because the gelatine has almost disappeared, but anyhow, it at one time had a gelatine surface. All sorts of gelatine-faced papers are used in the same way, as, for example, type temporary support. If you want something unusual in way of transfer papers, you will have to experiment for yourself. We should advise you to study Fritz's "Photo-Lithography."

STUDIO.—We believe you will be liable for the rates from the commencement of your tenancy. The fact that you pay no rent has nothing to do with the municipality.

R. P. S.—The following and closing lecture will be delivered at the New Gallery, Saturday, October 26, "The Beauties of the High Alps," by Louis J. Steele, M.I.E.E., member of the Alpine Club.

*\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.*

## SUMMARY.

The exhibition of portraiture by artificial light opens this day at the house of the "B.J.," and remains open until November 30.

Review of the exhibition, pointing out the results accomplished by the various systems, "Westminster" enclosed arc, mercury-vapour, "Morgan," "Adamson," etc., appears on page 824.

An account of some further tests of the "Jupiter" arc lamp appears on page 825.

The first chapter of a series of abstracts of recent papers on artificial lighting, by Baron von Hübl, will be found on page 826.

"Photograms of the Year," just published, will be found an admirably illustrated survey of recent pictorial work in photography. Our review of its illustrative and literary contents appears on page 831.

Silver phosphate emulsion, a process of screen-plate photography, and a three-colour camera, are among the patents of the week. (P. 829.)

Autochrome flower studies.—A note on the æsthetic side of this variation of the Autochrome plate appears on page 822.

The will of the late Mr. A. L. Henderson is quoted on page 835.

Mr. A. Lockett makes a suggestion as to stereoscopic effects in artificial illumination. (P. 828.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Replicates of Autochromes.—Mr. C. Welborne Piper records the results of experiments in making contact and reduction copies of Autochrome negatives and positives. (P. 81.)

Mr. Alfred Watkins shows that a panchromatic meter paper is likely to prove a more reliable guide to the exposure of Autochromes than the present three-speed method. (P. 82.)

Auto-micrographs of the Warner-Powrie screen-plate have been made by Mr. Martin Duncan. (P. 83.)

Apparatus makers have been active in offering accessories for use with the Autochrome plates. Three patterns of whirler and a developing dish to prevent frilling are reviewed on page 85.

A chemical-toning method for making three-colour transparencies is recommended by a German worker. (P. 84.)

## EX CATHEDRA.

### The Artificial Light Exhibition.

We hope that of the many professional readers who address us on the use of artificial light for portraiture, all those who can do so will take the opportunity of seeing the 130 examples now collected at the house of the "B.J.," and to be seen by every visitor. We notice the exhibition at some length this week, and we shall, within the next week or two, give special attention to the present systems of artificial lighting in the shape of articles on the use of enclosed arc lamps, the mercury-vapour light, and on the general principles which underlie artificial illumination. The exhibition remains open until November 30.

\* \* \*

### Testing Lenses.

Mr. Chalmers, in his Traill-Taylor Memorial lecture, expressed the opinion that a lens should be considered quite satisfactorily corrected if it represented a true point of light by a disc or patch not exceeding one-thousandth of an inch in diameter in the centre of the plate, or by one four times as large at the margins of the plate. Of course, the marginal definition can never be so perfect as that in the centre, and an allowance must always be made for this. Many inexperienced people, however, are not aware of this fact, and they are very apt to unjustly condemn a lens that they have submitted to a test that is really somewhat too critical for their comprehension. If an artificial "star" is made by placing a very strong light behind a very small pin-hole, and this is used as a test object, many lenses of really fine quality will appear to the inexperienced to be behaving very badly near the margins of the plate. With such a test it is easy to detect obvious traces of astigmatism and coma, even in a very good lens, but it is also easy to forget that these appearances may be of no consequence. Very much depends on the distribution of the light in the patch observed. If there is a very small disc or patch that is brilliantly illuminated, and a coma wing that is very faintly illuminated, the lens may still behave very well indeed in practice, for though the wing may be visible in the circumstances of the test, it does not follow that it will affect the plate. Indeed, it is often an extremely difficult thing to secure a photographic impression of it at all under the best experimental conditions. In practical testing, a good deal of judgment has to be exercised in discriminating between appearances that are important and those that are of no possible consequence. Hence the casual purchaser of a lens is well advised if he confines his own experimental tests to actual exposures in the camera in the conditions under which he will generally use the lens. If he endeavours to apply more scientific tests hurriedly picked up out of text books, he will probably misjudge the lens altogether.

### Flower Studies in Colour.

The Autochrome plate has tempted many photographers to produce flower studies of a kind that show they have hitherto given little attention to still-life work. Of course, the fact that the process is so new may have impelled them to give more attention to the properties of the plate than to the arrangement of their subjects, for many of the results are excellent advertisements for the plate, though very few are good flower studies. Still, it is rather noticeable that workers who show plenty of restraint, and evidently appreciate the value of simplicity in their monochrome work, should yield to the temptation to revel in gorgeous colour contrasts and over-complex detail in their Autochromes. Enough experience has been gained with the Lumière plate to show that it offers opportunities to the flower photographer that are unique and of great value, if only he will give his attention to and concentrate his energy upon the flowers. In many of the studies that have been on view, the flowers are spoilt by the juxtaposition of drapery, old china, and varied bric-a-brac that is only detrimental to the effect. Metal bowls, china vases, elaborate tablecloths, and hanging drapery are not wanted. In colour they are even more obtrusive than in monochrome, and in many cases the attempt to preserve their true colours has caused the correct rendering of the flower tints to be neglected. While the Autochrome process seems to be far ahead of other colour processes in the literal truth of the colour rendering, yet it is hardly quite perfect in this respect, and in a long scale of very varied colours some are not represented quite so accurately as the others. Some seem to require more intensification than the rest, therefore the truest general effect is obtained when the range of colour is not too varied. In a flower study the whole interest is naturally concentrated in the flower, and a true rendering of it is of the first importance. In many cases, however, it is obvious that the photographer has refrained from intensifying his flowers up to a sufficiently rich tint, for fear of over-intensifying sundry gorgeous accessories that would have been better left out of the subject altogether.

### Intensity of Diffused Daylight.

Professor Olin Basquin, of Chicago, has been measuring the intensity of diffused daylight received from the zenith at different seasons and times. We have not seen any description of this method of measurement, so cannot say whether he measured it photometrically or not; but, in any case,

it would seem that the results should have some bearing on the question of exposure with photographic plates. He found that the average intensity of the light during November, December, January, and February is only one-quarter that of June, July, August, and September. Averages are very deceptive, but it is interesting to compare this one with the relative values for diffused daylight in December and June according to Welcomme's Experimental Record. This ratio is one-third. As regards the variations at different times of the day, Prof. Basquin found that the average light at 9 a.m. was two-thirds as great as at midday, while at 4 p.m. it was but one-quarter. The ratio is therefore 8 to 3 at 9 a.m. and 4 p.m., which is a considerably greater difference than that allowed for in Welcomme's tables. The variations found by Prof. Basquin are therefore all greater than those allowed for in the tables, which is a somewhat curious result. The measurements are visual ones. If they are photometric the differences are too great to be satisfactory, for it is well known that the relative light values given in the tables are fairly accurate guides in matters of exposure. Probably the discrepancies are due to the method of taking averages, which cannot possibly give any useful information for photographic purposes, and is not likely to be of any use for any others. For the middle half of the year the ratio of the intensity at 9 a.m. and 4 p.m. are fairly constant, varying only from 3:2 to 4:3. For the rest of the year they are very variable, ranging from 2:1 to almost any conceivable ratio. The average for the whole year is therefore a very misleading quantity.

### View Meters.

It is a little astonishing that so many outdoor workers make no use of the view meter, seeing its great convenience. In conversation with several amateurs lately on the subject we learned that some of them did not even know of the existence of such an instrument. Probably, if they did they would not use it without one. In principle it is a reversed Galilean telescope on a small scale. An ordinary opera-glass is really a Galilean telescope, and is quite familiar to every one. In that the large, or field-glass, is a positive lens, the small, or eye piece, is a negative one. If we look through a reversed way through an opera-glass we see the scene a diminutive scale, and at an apparent long distance. Now in the view meter the field-glass is the negative and the eye one the positive. These are mounted in a tube sliding in another, which is fitted with a diaphragm.

## THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

Among other alterations and improvements which have been made in the forthcoming volume, the publishers beg to announce that:—

All three indexes (text, advertisement, and trade addresses) will be found AT THE END OF THE VOLUME.

The size of the volume has been appreciably reduced, without sacrificing the value and scope of the contents.

The editorial article will deal very completely with the important subject of—

SCREEN-PLATE THREE-COLOUR PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The 1908 ALMANAC will contain as frontispiece a colour print by the Autotype Co., dry-mounted by the Adhesive Dry Mounting Co., Ltd. Amongst other attractive features it will be found a specimen of three-colour printing by Sanger-Shepherd Colour Printing Co. and examples of three-colour work of Hood and Co., Ltd., Middlesbrough.

Our publishers desire us again to caution our readers against postponing the booking of their copies of the ALMANAC.

### PUBLISHERS' NOTICE.

The publishers beg to inform agents that it will be as well to place their orders for copies immediately, as the issue is always booked before publication, and a second edition will not be printed.

shape of which corresponds with that of the plates employed. On looking through it the view is seen through a diaphragm, and by drawing out the tube the angle is more or less curtailed. The sliding tube has marks on it which show what amount of subject will be included on the plate by a lens of any given focus. Say, for example, we are using a half-plate camera with an eight-inch focus lens, if we draw out the tube to the mark for eight inches, we then see at a glance what will be included in the negative. Other marks will show what we shall get with lenses of longer or shorter focus as the case may be. In this simple instrument we see directly how the picture composes, and by viewing the scene through it at different points we can tell where the camera should be placed to get what we desire, and what focus lens should be used. Thus we can avoid repeated shiftings and refittings of the camera, and also dispense with trials of different lenses one after the other.

### PREPARATIONS FOR THE WINTER.

At the eve of winter the question naturally arises as to what there are not a number of preparations for the winter season which are best made before its more immediate approach. One of the first things which should be seen to is the roof of the studio. It may or may not be in a thoroughly watertight state; if it is not, it is better to carry the repairs while the conditions are favourable. Nothing much more annoying than to find that the rain has had its way through the roof and dropped on to some lovely accessory, or perhaps ruined a good background. Annoyance is not tempered by the knowledge that the trouble might have been avoided had a coat or two of paint and a little putty been applied to the outside of the studio beforehand. The photographer will be wise now to examine thoroughly the outside of the studio, and if they show signs of cracking away from the sashbars to see it hacked out and fresh applied after a coat of paint has been laid on the bare parts. If this is done a subsequent couple of coats of paint will make the roof safe against rain. It is well, while this work is in hand, to keep in mind that melting snow will often find its way through where rain will not. If the weather will permit of the old putty being removed and the work done afresh, the next best thing, perhaps, is to paint over the sashbars and old putty carefully with gas tar, to which a little tallow has been added. This is very repellent of water, and enters well into the cracks. It should be applied as hot as possible, as it is then very fluid and penetrating. While this work is being done the outside of the glass should be cleaned, for, in large towns especially, it is often coated with a very non-actinic film that cuts out a deal of light which cannot well be afforded during the winter months.

Another important matter for consideration is the warming of the studio and dark rooms. Undoubtedly hot water is the most cleanly, and in the end the most economical source of heat, since one fire will do for the whole series of rooms. Furthermore, by regulating the temperature of the furnace the fire can be kept continually burning with a small consumption of fuel, so that the place can be kept at a genial temperature through the night for the next morning. On the other hand, if the fire is not kept in all the time it must be lighted an hour or two before the heat is required, as the water takes a long time to circulate through the pipes. Also, during a hard frost, it is necessary that the fire must be kept alight; otherwise there is the danger of the water freezing in the pipes.

Gas as a source of heat is very cleanly, and at the same

time very convenient; but it is by no means economical unless one is content to have the products of combustion in the studio, and they are by no means either pleasant or healthy if inhaled for any length of time. If a flue is provided to draw them off much of the heat is carried away with them. The most economical stove, if one does not mind the fumes in the place, is, probably, what is known as the "Chancel," made by Fletcher and Co. at a very moderate price. It lies flat on the floor, and gives off a good heat. As the laps of the glass in most studios are generally open, the fumes can escape between them, so that they are not so very unpleasant. If a tray of water is placed underneath or beside the stove much of them are absorbed by it.

Closed and semi-closed stoves of the slow combustion type are, perhaps, the most generally used in studios, and, on the whole, are probably the best. They give out a good heat, require but little attention, and are very economical in use. Charged with fuel in the morning they will last the day through, and if again charged at night and the dampers regulated they will keep alight throughout the night. If the fire is made up on Saturday night even, and the dampers nearly closed, it will last till Monday with but a small consumption of fuel. These stoves are suitable for coke or coal, or a mixture of the two. A drawback to some of them is that the fuel is consumed to a very fine ash, and a good deal of dust is created when it is raked out, unless that is carefully done. Heating apparatus of this type is very moderate in price. A plain stove, sufficient to heat a good-sized studio, say, about 25 ft. by 12 ft., costs only about five-and-twenty shillings. More ornamental ones, of course, cost more. Messrs. Smith and Wellstood, Ludgate Circus, have a great variety, some of which are very ornamental, yet not at all costly. It goes without saying that all these stoves require a flue-pipe, and if there is not a chimney near into which it can be connected the pipe must be carried through the roof of the studio. When that is done it is advantageous to have the pipe as long as it can conveniently be, say, by carrying it up at a slant instead of vertically, as then most of the heat passing up it will be radiated in the room. In connection with pipe stoves, it should be mentioned that the insurance companies do not look upon them with any great favour, and therefore one should not be installed without notice being given to the company, or the policy may be invalidated.

Another matter for consideration is the warming of the dark room, for if that is cold things do not work well. There will be a difficulty in getting full detail in the shadows and density in the negatives if the temperature is much below 60 degrees. The indoor temperature should be 65 deg., or 70 deg. is better in cold weather. A small Bunsen gas stove near the floor will keep the room and its contents at a comfortable heat; but if this method of warming be adopted, the stock of plates and paper should not be kept in the room, or they may suffer from the fumes given off. In place of gas, a paraffin stove may be used. If it be kept clean and the wick rightly trimmed no unpleasant fumes need be given off; yet in the event of the stove burning badly the fumes from it are not likely to be injurious to either plates or papers. An ordinary paraffin lamp, with a three-quarter or one inch wick, if left burning all night in a small dark room, with the door shut, will keep it, the dishes, and solution at a working temperature. It is always better that the developing dishes and the different solutions be kept constantly at a proper temperature than to have to warm them up every time they are required for use. When the latter plan is adopted it not infrequently happens that an error is made in the opposite direction.

## THE EXHIBITION OF PORTRAITURE BY ARTIFICIAL LIGHT.

THE collection of work gathered together in the little gallery at the offices of "The British Journal of Photography" illustrates very comprehensively the various aspects of artificial light portraiture. To mention the systems of lighting represented would involve a list of considerable dimensions, for several lamps are used in various ways, for example, with direct light, or with reflected light only. The examples are produced with magnesium flash, open arc, enclosed arc by various makers, Morgan filtered light, Adamson super-incandescent, and the mercury-vapour lamps, and the educational value of the exhibition has been rendered much greater by indicating in the catalogue the system and method of using it which has been employed in each case. One is first of all impressed afresh with the fact that, after all—as, of course, every one would expect—much more depends on the man than on the lamp. Where one is familiar with the daylight productions of any of the workers, the same characteristics are to be seen in these artificial light examples, a pretty clear indication that the distribution of the light is under control and that matters are bent to the worker's will. Ten years ago such a collection, gathered from so large an area, would have included examples showing harsh lighting and heavy shadows. The prints before us, with scarcely an exception, show neither the one nor the other defect. Not only have the mechanics of the use of artificial lighting methods been mastered, but the tools are sufficiently under control in most cases to admit of the production of artistic effects of light and shade.

The Schroeder flashlight apparatus is represented by some fine examples from Herr R. Dührkoop, of Hamburg. The negatives might be regarded by a technician as tending to under-exposure, but so cleverly is the arrangement of lights and darks managed that the effect is one of great richness and strength. The shadows are exposed enough to avoid large masses of even tone, and, as the area of shadow is large in each case, the gradation present is amply sufficient to produce transparency. No. 105, "Duft," is a novel portrait of a girl, apparently an excellent likeness, yet interesting apart from any question of acquaintance with the sitter. A number of other examples by able Continental workers are also produced with the Schroeder magnesium flash lamp.

The well-known Todd-Forret magnesium flash, which hails from north of the Tweed, is appropriately represented by a specimen by John Moffat, of Edinburgh. This is a large stage group of a couple of dozen figures, in which there is perhaps some heaviness of the flesh tones, suggesting a tendency to under-exposure.

Other examples by John Moffat are studio portraits by the Adamson super-incandescent lamp, and some fine work, particularly a delicate and vivacious child study, from Medrington's, of Manchester, is also taken under this lamp.

The mercury-vapour, as one of the later comers, holds its own well. Some of the work is done by the Cooper-Hewitt, and some by the lamp made by Schott, of Jena, and for which Mr. A. W. Isenthal is the British representative. J. Mallia, of Oxford Street, W., shows three large specimens of feminine portraiture, which are undeniably effective, even if rather too dramatic for ordinary private portraiture. The specimens by C. David Kay, formerly at the Regent Street Polytechnic School of Photography, and now head operator in a Dublin studio, show that with the mercury lamp it is possible to secure great delicacy of modelling and excellent rendering of draperies. George R. Henderson, of Hebburn-on-Tyne, has one or two mercury lamp portraits of such well-known men as Pete Curran,

M.P., and "Sub Rosa," in which last the flesh modelling rendering is excellent. The Dover Street Studios and Adolphe Langfier, of Wigmore Street, W., exhibit work which shows that the lamp is as suitable for strong effects on the hand as for delicate child studies on the other.

Quite a little crowd of workers use enclosed arcs, either supplied by the Westminster Engineering Company or Jandus lamp. Much has been done by the use of this for popularising it for portrait work, and Mr. David Kay's special show what may be accomplished by a student, presumably learning the use of an artificial light installation. The portraits of Mr. C. H. Hewitt, of the Polytechnic School, should be noted for the delicate rendering of fleecy drapery, which looks though a puff of wind would stir it. The tonal relation of flesh, and drapery is also very pleasing. Mr. J. C. Leon has an excellent set of portraits produced with reflected light while some very fine pictures by Scott's Studios, Ltd., of Regent Park, N.W., are done with the Morgan system with additional Westminster enclosed arcs. Mr. W. H. Baylis, of Eccles, David Kay both show some large work taken direct, the latter portrait of S. G. Kimber, Esq., F.R.P.S., being a characteristically good likeness. Andrew W. Dron, of Brondesbury, uses the Westminster Arc with reflected light only, and with both reflected and direct light, and his results amply justify either method of arrangement, while the admirable work by H. Edmonds, Ltd., of Holland Park Avenue, W., done with Westminster Arcs arranged on the artist's own system, are sufficient to convince Mr. Hull an authority on the question of installations. Pictures by Short and Wood, of Ramsgate, and by J. J. Webb of Bradford, with Westminster and Jandus enclosed arcs respectively, are good commercial work.

The Boardman system of open arc is represented by an extensive display of work from the well-known studios of A. Ellis and Walery, of Baker Street. If it is remarked that the pictures are indistinguishable from the best daylight productions of the studio from which they emanate nothing further is necessary as an indication of their quality. The Elite Portrait Company, of High Holborn, show a couple of specimens of work with the same type of lamp, the portrait of The Hon. Bruneau being noteworthy on account of the very effective concentration of light near and on the head. Polsky Brothers, Whitechapel, exhibit a couple of effective costume portraits which are straightforward commercial work.

The specimens of work done with the filtered arc are light on Morgan patent system are by Morgan's Aberdeen studios, amply demonstrate the excellence of the method.

Work by Turner and Drinkwater, of Hull, and by Speake Ltd., of Bond Street, W., by arc lamps, particulars as to maker or arrangement not being given, are in both cases what we should expect to see from the workers who have produced them. Beautiful technique showing a complete mastery of the manipulative details, the sympathetic handling of the subjects bespeaking the feeling of the photographer, and the general arrangement of line and massing of lights and shades indicative of artistic training and temperament.

Some examples of work done with the latest claimant for popular favour, the Jupiter flash electric lamp, are also exhibited, being produced by various Continental workers.

The collection as a whole is one which every worker using artificial light or contemplating its installation should make effort to see and carefully study. The exhibition opens to-day, November 1, and will remain open daily from 10.30 till 4.30 to the end of the month.

## SOME NOTES ON THE JUPITER ARC LAMP.

THE German arc lamp which is being placed on the British market by Messrs. J. J. Griffin and Son, of Kingsway, presents many interesting features, and the present moment, when the exhibition of artificial light portraiture at the "B.J." "little galleries" is just opened, is a very opportune one for calling attention to its novel points, and the advantages which may accrue from its use.

The lamp differs from ordinary arcs in that it is a flash lamp (not to be confused with the magnesium flash). The carbons are rapidly separated at the instant the current is allowed to pass through them. The mechanism by which this is effected is ingenious and yet simple, and it is possibly more interesting to an electrician than to the photographer, who will wish to be acquainted with the photographic capabilities of the instrument. Suffice it, then, to say that the light is of extreme actinic power while the duration of the flash is estimated by the makers at 1-40th of a second. Most readers will be familiar with the flash which frequently illuminates the tunnels of the underground electric railways, or the flash from overhead wires of electric tramway systems when there is a break in the contact for a fractional part of a second. This is very similar to that intentionally produced by the "Jupiter" lamp. The intense actinic power, coupled with the extremely short duration of the flash, gives the studio worker certain advantages with naturally some slight compensating disadvantages, and to summarise these is the purpose of the present article.

### The Boon of Rapid Exposure.

Any studio portraitist who sets naturalness before conventionality, and who is anxious to break away from the stiff and "posed" portrait traditions, will welcome a method of work which should enable him to chat with his sitter over a few curios, a portfolio of etchings, or any other object of interest, and to make his instantaneous exposures at those moments when there is a happy combination of pleasing expression and satisfactory line. How often these occur for a fraction of time, to disappear the instant the photographer endeavours to take a cessation of movement for his exposure, none know so well as the experienced studio portraitist. With a suitably constructed reflex camera, too, on a very rigid stand, children's portraits may be done whenever a suitable pose or grouping presents itself, raising the mirror and instantly giving the flash for the exposure. In this way the picture may be kept in focus up to the moment of an exposure, which is too brief to show any average movement. It will, of course, be readily understood that the sitter must not be allowed to move too far away from the lamp, or there will be some likelihood of the shadows being under-exposed and heavy, but it is fairly easy to control the movements of a child at play, so that the variations in position shall not be more than a distance of three feet from any determined spot, and the light is sufficiently powerful to allow of as much variation as this.

The question will occur to the experienced portraitist, is a very rapid exposure suitable for securing either pose or expression? The snapshot not infrequently shows us the well-known effect of a man tripping across the street, and if this is so with often the exposure of 20th second, what kind of attitude may we expect with 1-40th sec.? It is, in the first place, not very likely that the movements of the sitter will be so violent as those of a man walking quickly even, and in any circumstances where high-class work is being produced, there are a number of throw-outs, it will not be surprising if a new method of procedure also has its rejected negatives. In regard to expression there may be rather more difficulty, for the best likenesses are often those in which a fairly full exposure gives a blend of

expressions. A very rapid exposure often tends to give one phase of the features only, and as this will occur with those subjects who are most vivacious, and whose charm we recognise, subconsciously, as consisting largely in their constantly changing aspects, the flash portrait may fail to please us. This, however, is theory merely, and we all know how often practical experience runs counter to theory, so that before any definite opinion can be formed, a large number of these flash portraits must be taken, and the views of qualified critics obtained on them.

### Some Tests of the Jupiter Lamp.

In some tests recently made one point of special interest cropped up. Some exposures showed the eyelids down, and as the flash is so rapid it was scarcely probable that the eyes had closed because of the flash. With a flash of longer duration this might occur. The explanation given by an experienced worker who was present, and one which is most likely the correct one, is that a blinking of the eyes had been photographed actually in progress. Persistence of vision is usually given as being the sixth of a second, and as we are not conscious when looking at anything of the occasional blinking of our eyes, the blink is less than this. About a twenty-fifth of a second is perhaps the approximate duration of a wink, and assuming that this is so, it would be possible to photograph the sitter while the eyelid was down over the eye if the blinking of the eyes and the flash of the lamp synchronised. This is an important point, and the operator must be an observant man, and must make his exposure immediately after he has observed the eyes blink.

The lamp is a convenient one to handle, and is well designed from a mechanical point of view. The arc is placed in a shallow basin shaped reflector, the direct light being diffused by means of a frosted glass shade. Round the reflector are placed eight ordinary incandescent electric lamps for general illumination and focussing purposes, and these give a comfortable light for working by. In front of the light is a large frame on castors, covered with butter muslin, and this gives a large area of diffused light, and consequently a soft and delicate illumination of the head and figure. Naturally a good sized reflector is needed for the proper lighting of the shadow side of the head.

For large groups where a little extra illumination may sometimes be requisite, the lamp may be used as an ordinary arc, and an exposure of, perhaps, a couple of seconds given, this being finished up with the usual flash to complete the exposure.

The basin shaped reflector carrying the arc may be raised or lowered on the metal stand by means of a little winch handle, and the inclination or tilt of the lamp is altered by a flexible connection from a small handle to an endless screw. The whole stand is very rigid without being unnecessarily heavy, the upright support being stayed to the base on castors by means of three chains, which are made taut by a novel method. As at present made, the lamp is flashed by means of a pneumatic release, another one being used for the shutter on the lens, but an obvious gain would result if one pressure on one ball only were to both release the shutter and produce the flash. Perfect synchronisation should result, and the shutter would not be likely to remain open long enough for lighting from the focus lamps on the sitter to impress the plate.

It only remains to add that the exposures made with the lamp on plates of about 200 H. and D., a quite ordinary speed for everyday studio work, were developed in a standard metal hydroquinone developer, and came up quite like normal daylight exposures.

"THE BOOK OF THE LANTERN."—A most exhaustive catalogue of lanterns, cinematographs, and accessory apparatus has been issued under this title by the Service Company, of 292 and 293, High Holborn. The volume runs to close on 200 pages, and is very fully illustrated. Its postage must amount to pretty nearly the sixpence for which the Service Company will send it, to say nothing of the cost of production. No user of lantern or cinematograph apparatus, we would say, can afford to be without such a comprehensive list. The price of the catalogue will be deducted from the amount of the first purchase.

CANVASSERS' METHODS.—A writer to the "Glasgow Evening Times," after uttering a warning as to the fraudulent nature of the "free enlargement" business, goes on to say, "About three months ago one of these gentlemen walked into my house and coolly took a photograph out of its frame and quite as coolly put it in his pocket, notwithstanding the protestations of an old woman who was the only occupant of the house at the time, and who was unable to prevent him. Since then I have called at their place of business several times to try to recover the photograph, but without avail. In fact, I got a great deal of insolence, and was not very politely shown to the door."

## ARTIFICIAL LIGHTS IN PHOTOGRAPHY.

(An abstract of recently published Papers by Baron von Hübl.)

THE first application of the electric light to photographic purposes was probably the experiments of Silliman and Goode in 1840<sup>1</sup>, when they photographed a medallion on a daguerreotype plate, but the first portrait was probably taken by Aubree, Millet, and Leborgne.<sup>2</sup> After this date numerous applications of the light were made, but it has only been within the last few years, since the great advance in photo-mechanical work, that its use has become general, and not only for illuminating the subject to be copied, but also for printing; Bedford<sup>3</sup> was apparently the first to use it for printing purposes.

FIG. 1.

It is quite unnecessary to trace its development, except to recall the advances in the shape of the enclosed arc (1895<sup>4</sup>), and the flame carbons, which are of much more recent date.

The following notes upon this subject are abstracted, with additions, from a series of articles by Baron von Hübl, in "Das Atelier des Photographen," and it is proposed to deal with the various appli-

I.

The first point to consider is the distribution of the light, in terms of its visual or chemical properties, and whilst we assume the light source to be a point it is not theoretically so; but for all practical purposes and when compared to the broad extent of a studio or daylight, we may assume that it is a point. The disadvantage of our point as a light source is that the distribution of the light is practically confined to a circle or a series of concentric circles, as shown in Fig. 1, in which  $L$  is the source of light, and  $k$  the inner circle and  $K$  an outer one, this being less illuminant naturally than the inner, and in proportion to their extent of surface. The surfaces of two spheres or circles, being as the square of their diameters,  $K$  is practically nine times less brilliantly illuminated than  $k$ .

Fig 2

When we come to deal with plane surfaces, as we do in photography and printing, the above law does not hold good. As will be seen by reference to Fig. 1, that at  $F$ , a plane surface is illuminated by  $4 \times 4 = 16$  beams, whilst if the distance is reduced one-third and the plane placed at  $F^1$ , it will be illuminated by  $10 \times 10 = 100$  beams; therefore the ratio is practically as 1:6 in the case of the circle. It is obvious, too, from a consideration of the figure that the decrease in illumination is greater towards the margins, as here the beams of light are spread out, and strike the plane at a greater angle.

In printing we have always to deal with extended surfaces, and therefore of interest to study briefly the law governing the distribution of the light over such surfaces.

Let  $L$ , Fig. 2, be the luminous point, from which proceed the directions rays of the intensity  $I$ , and let the plane surface

Fig. 3.

cations, the advantages and disadvantages of the electric light, and mainly the arc, and the mercury-vapour lamp.

In dealing with this subject it is essential to differentiate sharply between visual luminosity and chemical luminosity, between the use of the light for photographing and for printing, and the reproduction of black and white and coloured objects.

<sup>1</sup> "Daguerrian Journ.," 1851, pp. 139, 334.

<sup>2</sup> "Daguerrian Journ.," 1852, p. 57. "Comptes Rendus," Vol. 33, p. 501.

<sup>3</sup> "Photo. News, 1861," p. 279.

placed at a distance  $A$  from the light source, then the point which the rays fall upright, will be illuminated with the intensity

$$E_0 = \frac{I}{A^2}, \text{ and for an object at } P \text{ at a distance } R \text{ the illumination is } E = \frac{I}{R^2}.$$

The angle  $\alpha$ , which  $P$  forms with the normal to the plane, is called the "angle of radiation," and is  $R \cos \alpha = A$  or  $R = \frac{A}{\cos \alpha}$ .

therefore the illumination of a plane placed at an angle to the normal is  $E_0 \cos^3 \alpha$ .

But this only applies when the surface  $f$  is at right angles to the incident rays, and has the position  $a$   $b$ ; but it is inclined to these at an angle  $\alpha$ , so that the beam of light is spread over a greater surface, and the illumination decreases in inverse ratio to the enlargement of the surface. The illumination of the plane  $f$  is therefore

$$\frac{E}{e} = \frac{I}{A^2} \cos^3 \alpha.$$

From these considerations it is obvious that the intensity of illumination is greatest in an upright direction from the light source, and decreases towards the edges in concentric circles, and in the ratio of the third power of the angle of radiation.

If the illumination  $E_0$  in the middle is taken as unity, that for all points at an angle  $\alpha$  (that is, all points on a circle the radius of which is  $M = A \tan \alpha$ ) is  $e = \cos^3 \alpha$ .

The values of the cosines and tangents can be easily found by reference to any collection of mathematical tables.

Practically when printing a negative, 20 x 20 inches square, at a distance of 20 inches from the light-source, the margins receive 75 per cent. and the extreme edges only 55 per cent. of the light that falls upon the middle. This point is rendered much clearer when the intensities are graphically represented. In Fig. 3 let  $L$  be a source of light placed at a distance  $A$  in front of the plane  $F$ . The

incident rays illuminate  $O$  with the intensity of  $E_0 = \frac{I}{A^2}$ , and

each point of the plane illuminated by rays at 10, 20, 30, etc., degrees, will from the above calculation be illuminated in an intensity of 0.94, 0.83, 0.66  $E_0$ , etc. If these values are drawn at right angles to the plane  $F$ , we shall obtain a curve  $C$ , which is called the "curve of illumination."

From a consideration of this figure it is very clear that the illumination of a printing frame decreases very rapidly with increasing "radiation angle," and if a difference of illumination, amounting to 10 per cent. between the centre and margin, is the maximum allowable, the printing frame must lie within a light cone of about 30 degrees. In printing from half-tone negatives these conditions must be fairly closely adhered to, that is to say, the distance of the light source must be about double the length of the frame. This is obviously a very extravagant use of the light, for the whole of the light incident on  $F$  is represented by the surface of the "illumination curve"  $C$ , and for printing the negative only the fraction  $a$ ,  $b$ ,  $c$ ,  $d$  is used. The light emitted from  $L$  can illuminate a hollow sphere of 34 inches radius, that is, can illuminate a surface of nearly 8 square yards as brightly as a frame of 12 x 16 inches, the area of which is only 192 square inches.

With less exact work it is possible to use an angle of 40 degrees, but in no case is it possible with a point as source of light to evenly illuminate any extended surface, therefore several printing frames should be used at once.

In printing from line or in blue printing the conditions are more favourable, and one can use a light-cone of 60 degrees—that is, the portion of the curve lying between  $A$  and  $B$ —without any troublesome difference in illumination. The distance of the light source may then be the length of the frame, so that the intensity of the illumination, in comparison with the previous case, is increased fourfold.

#### The Use of Several Light Sources.

We have seen that one point of light cannot evenly illuminate an extended plane, and if the printing frame is placed near the light the differences are increased, whereas if the frame is moved further away in order to obtain more even illumination it becomes too weak, and the greater part of the light is unused.

In order to obtain a homogeneous plane field of light of greater extent it is necessary to use several lights. Let  $L$  and  $L_1$  represent the two lights, and  $F$   $F$ , Fig. 4, the illuminated plane, then the two curves  $C$  and  $C_1$  represent the distribution of the illumination at any point. The total illumination of each point is then obtained by adding the individual illuminations; thus the point  $a$  is illuminated by  $L$  with the intensity  $a$   $b$ , and by  $L_1$  with the intensity  $a$   $c$ ; therefore the total illumination is  $a$   $b$  and  $a$   $c$  =  $a$   $d$ . In this way we obtain the dotted curve  $C_2$  as the total illumination. The distance  $L$   $L_1$  can be so chosen that combined illumination becomes

practically homogeneous for an extended surface. This is, as shown in the figure, the case for the distance  $L$   $L_1$ . To do this the two lights must be at right angles to the plane  $F$   $F$ , and so that each is opposite that point at which the other light forms an angle of 50 degrees.

The distance  $D$  between the two lights is so chosen that  $D = A \tan 50$  degrees, that is,  $D = 1.2 A$ , when  $A$  is the distance between the lights and the plane  $F$   $F$ . If the lights are further separated there appears between them a minimum of illumination. If, on the other hand, the distance is decreased a maximum of illumination appears. If, as has already been assumed, a difference of illumination of 10 per cent. is permissible, then  $D$  may equal 1.5  $A$ .

In this way one obtains an evenly illuminated strip of 1.5  $A$  in length, and 0.5  $A$  in breadth, so that to evenly illuminate a square four sources of light are required. This combined illumination is always used for negative work, and when a light is placed on each side of the camera with a separation of 39 inches, and a distance from the copy of about 30 inches, the illuminated field is 39 inches long and 19 inches wide, and four such lights illuminate a square yard.

For illuminating printing frames this arrangement is not so satisfactory, for Fig. 4 shows that, beyond  $L$   $L_1$ , the intensity of the

Fig. 4.

curve  $C_2$  rapidly falls off, so that it can only be used for very large work, such as blue printing, etc.

Another method of evening the illumination is either to keep the printing frame or the light continuously moving. As a rule, after the necessary exposure the frame is turned 180 degrees, and very large frames are turned 90 degrees after every quarter of the time exposure.

#### Reflectors.

The light that streams from the back and the sides can be utilised by means of reflectors. The most efficient is the arrangement used in searchlights, but it is costly and easily disarranged.

Polished reflectors of any kind are useless, since, on account of their incorrect shape, they throw zones of different intensity and lines of light, which are noticeable in the print. Matt white reflectors should alone be used. A ray of light falling on such a surface is not reflected in any particular direction but in all; in fact, matt reflectors act as a second source of diffused light, intensify the illumination of the light source itself, and, from their size, produce a relatively even field of light. The larger the reflector the more evenly it distributes the light over the plane, but the more the light that falls at

the sides is unused. When there is even an illumination as possible is desired, the reflector should be about the same size as the surface to be illuminated.

The shape of the reflector is not of much moment, as long as it is given a curved shape, and naturally one would conclude that a hemispherical one would be the most satisfactory; but as an arc does not emit light upwards and downwards, a half-cylinder is quite as effective.

All white or enamelled substances gradually turn yellow under the great heat, and in a short time reflect only the less refrangible rays, which have little influence photographically. As a rule, reflectors are much over-rated, and their chief use is to protect the operator from the blinding rays of light.

#### Photo-Chemical Luminosity.

An ordinary photometer, as used for measuring the visual luminosities, gives us no indication of the photo-chemical luminosities, for in the former case it is the less refrangible rays which are used in measuring. These have no effect in ordinary work, such as negative making and printing. As an actinometer Von Hübl uses a strip of collodio-chloride P.O.P., fastened to a dark grey paper. This he exposes to the light till the two are of uniform tint, using a green glass to obviate the difference in colouring. That this method is not free from objections is obvious, but as the variations in an arc are always so great and the method is used for practical and not theoretical photo-chemical investigations, we can dismiss these objections as of little moment.

#### STEREOSCOPIC BOOKS AND MAGAZINES.

It does not seem to have occurred to anyone—at all events the idea has not been put in practice—that the mirror stereoscope, invented by Professor Léon Pigeon, of Dijon, is admirably adapted for use in conjunction with specially illustrated books or magazines.

Scientific, technical, and educational works, or books of travel and adventure, as well as high-class pictorial magazines, would gain enormously in interest if illustrated with a series of stereograms, bound in with the text on stiffer pages. The method in which the mirror stereoscope could be made a permanent part of the book is shown by Fig. 1. A light metal frame, larger than the pages, is hinged in the centre of the cover, and in this frame is pivoted a thin wooden panel having a silvered metal mirror let into it at the top.

When it is desired to turn over a leaf in order to look at a fresh picture, the panel with the mirror is swung up, by pressing with the fingers on the top; the leaves will then pass through the frame in

Fig. 1.

either direction, as shown in Fig. 2. Small stops or projections are placed at intervals round the inside of the frame so that the panel will only rise at one side, and is checked in the correct position when permitted to fall.

As regards the angle at which it is requisite for the pictures to be held, no difficulty will be found. The right side of the book is allowed to rest flat on the table, the mirror panel being supported by the right hand, and the left side of the book is raised until the two views coalesce. This can be accomplished in a few seconds, and, once tried, the adjustment is thereafter made instinctively and without trouble. The thin panel and mirror will lie flat in the book when closed, while the frame being larger than the pages will come outside them.

In all probability it would be held that the foregoing idea is covered by the original patent of the inventor of the stereoscope, although this particular application does not appear to have sug-

gested itself to him. The possibility of having a library of useful and instructive books filled with stereographic illustrations and each carrying their own stereoscope is, at any rate, well worth trying. Consider, for example, how interesting an astronomical work would be if illustrated with stereographic star maps; or the value to the medical student of a treatise embellished with stereoscopic pictures clearly portraying the exact position of every muscle and tendon. Such books would necessarily be expensive, but they would certainly find a ready sale. Within limits, the books and pictures could be of any

Fig. 2.

desired size or shape. The insertion and binding of suitable photographs, collotypes, or half-tones should present no real difficulty in these days of publishing enterprise.

An even simpler method than that previously described would be to have the mirror on a loose panel, which could be held in the hand; but this plan is not so convenient. The height of the panel would not be suitable indiscriminately for various sizes of books, nor would the adjustment be so easy or exact.

A. LOCKETT.

#### THE SOCIETY OF COLOUR PHOTOGRAPHERS.

##### AN ECHO OF THE EXHIBITION.

THE first annual exhibition of the Society of Colour Photographers, which was held at the house of "The British Journal of Photography," from September 30 to October 26, proved an undoubted success. The increased interest which is being taken in colour photography was evidenced, not only by the fact that the exhibition was visited by several thousand persons from all parts of the United Kingdom, together with a number of visitors from other parts of the world who are at present staying in London, but also by the fact that the most adverse conditions of weather failed to damp the enthusiasm of those who took the occasion of visiting a collection quite representative of the latest introductions and achievements in colour photography. The visitors' book contains, amongst many pages of signatures, those of Miss S. A. Acland, A. L. Adams, A. W. W. Bartlett, R. Child Bayley, Francis T. Beeson, Gerald Bishop, T. Bolas, Arthur C. Brookes, Warwick Brookes, Edwin T. Butler, D. Cameron-Swan, E. H. Carpenter, Gordon Chase, E. Clifton, A. Langdon Coburn, Frank Colebrook, F. Martin Duncan, Howard Elliott, Alfred Ellis, Frederick H. Evans, E. W. Foxlee, W. Friese Greene, S. Herbert Fry, Harold Furniss, W. Furze, John H. Gear, E. Greenwood, A. Horsley Hinton, Chas. E. Houghton, H. Edmunds Hull, Chapman Jones, Dr. B. Jumeaux, S. G. Kimber, Rev. F. C. Lambert, Harold W. Lane, J. McIntosh, A. Mackie, Hector Maclean, Thomas Macwalter, Ernest Marriage, Dr. C. E. K. Mees, Ward Muir, A. J. Newton, Arthur Payne, Otto Pfenninger, Paul Ponge, John H. Powrie, G. E. H. Rawlins, J. W. P. Rawlins, P. R. Salmon, E. Sanger-Shepherd, Edgar Scamell, George Scamell, Edgar Senior, Dr. S. E. Sheppard, James A. Sinclair, Edmund J. Spitta, A. E. Staley, W. Thomas, T. C. Turner, Miss Agnes B. Warburg, J. C. Warburg, H. Snowden Ward, Miss Florence M. Warner, Major-General J. Waterhouse, Alfred Watkins, J. B. B. Wellington, Alfred Werner, and Sir Henry Trueman Wood.

##### NEXT YEAR'S EXHIBITION.

At the annual meeting of the society, held towards the close of the exhibition, it was arranged that a second exhibition should be held, also at the house of the "British Journal," in the early summer of next year; and it is hoped that the success achieved by the first will be largely surpassed by the second, not only on account of the stimulus and encouragement which the recent success must have given to the

ent members of the society, but also from the fact that, by what this young society has already achieved, many other workers may be induced to take advantage of the privileges conferred on those who associate themselves with it. The sec., Mr. Henry J. Comley, Surrey House, Stroud, Glos., will be glad to give information as to the work, aims, etc., of the society to any who may apply to him at the above address.

## Patent News.

*process patents—applications and specifications—are treated in the Mechanical Notes.*

The following applications for patents have been received between October 14 and 19:—

**AIR APPARATUS.**—No. 22,697. Aerial photographing apparatus. George Raymond Lawrence, 52, Chancery Lane, London.

**GRASSES.**—No. 22,799. Camera to produce stereoscopic negatives. Franz George Reinke, 37, West Nile Street, Glasgow.

**LIGHT DEVELOPING.**—No. 22,844. Improvements in and relating to daylight developing apparatus for the development of photographic and the like films and paper negatives. Sidner Herbert Bath, Holly Cottage, West Street, Carshalton, Surrey.

**MATOGRAPHS.**—No. 22,874. Improvements in or in connection with light cut-offs for cinematographs and the like apparatus. John William Harris, 30, Park Row, Leeds.

**PERIMETERS.**—No. 22,995. Improvements in colorimeters. Jan Zeppezanik, 6, Bank Street, Manchester.

**LENSES.**—No. 23,020. Improved shutter for photographic lenses. Henry Arthur Byers, Fife House, Kingston-on-Thames.

**GELATINE.**—No. 23,030. Improved preparation of gelatine. William Henry Perkin and Whipp Bros and Todd, Ltd., 47, Lincoln's Inn Fields, London.

**PAPER.**—No. 23,118. The use of transparent paper or similar or textile material for the production of prints and photographs and of colouring them. Gustav Palmer Harding, 53, Sunderland Road, Forest Hill, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**SILVER PHOSPHATE EMULSIONS.**—No. 9,855, 1907. The invention is an improvement on that of Patent No. 9,993, of 1902, in which silver phosphate and silver chlorate with the silver salt of an organic acid are used, the two latter being soluble, whilst the phosphate of silver is insoluble. In order to produce greater sensitiveness this mixture is now used in excess, that is to say, such a quantity of the phosphate is incorporated that the whole quantity of silver is obtained or precipitated in the form of insoluble phosphate of silver, chloric acid and an organic acid being also present in the emulsion. The emulsion is made as follows:—

In presence of the known colloidal substances, preferably gelatine, a considerable excess of alkaline phosphate, preferably phosphate of sodium, is mixed with nitrate of silver. It has been found best to use double the quantity of alkaline phosphate, which would be necessary to convert the silver nitrate into silver phosphate. To this mixture chlorate of potassium and citric acid are added, and for the purpose of rendering the photographic emulsion more resistant, it may be desirable to add further a small quantity of chrome alum. Owing to the great excess of alkaline phosphate the whole amount of silver in the emulsion must be present in form of insoluble phosphate.

Experiments have proved the emulsion to be so sensitive that it may be used also for enlarging purposes and even for negative-making. The best developer for this emulsion is a simple aqueous solution of metol. The pictures show great intensity of brilliancy and very nice tones, and furthermore great permanence. By adding sulphite of sodium to the aqueous solution of metol the rapidity of development is so increased that it takes place nearly instantaneously, the development in this case being a chemical one. York Schwartz, 3, Eden Strasse, Hanover, Germany.

**SCREEN-PLATE COLOUR PROCESS.**—No. 6,098, 1907. The invention relates to the process of preparing a three-colour filter-screen for direct colour photography. By means of suitable printing apparatus, the primary colours are arranged upon the medium or backing intended to receive the sensitive layer or else upon the sensitive layer itself, preferably in the form of very fine lines. These lines are arranged in such a way that the primary colours lie one above the other and crossing each other, whereby an extraordinarily regularly distributed multicoloured linework is secured.

In Figs. 1—3, *a* is the support—e.g., a glass plate intended for

Fig. 1.

the reception of the sensitive coating. The compound line-work *b*, in the primary colour red for instance, is impressed upon this plate. The line-work is extremely fine, and the several lines are spaced off from each other at regular distances. The lines may be straight or curved ones, and they may also be composed of regular or irregular geometrical figures (for instance, circles or triangles, or the like—Figs. 4 and 5), arranged in a series of

Fig. 2.

Fig. 3.

straight lines, preferably running parallel to each other. The plate provided with the compound line-work, in the red primary colour for instance, is now turned preferably through an angle of about 60 deg., whereupon, as may be seen from Fig. 2, the second primary colour *c*, blue for instance, is imprinted on the plate by means of the same printing or pressing device. At the point where the two colours overlap or are superimposed violet will be produced as a compound colour. Now, if this plate be again turned through an angular movement of about 60 deg., and be printed as shown in Fig. 3 with the third primary colour, or

Fig. 4.

Fig. 5.

in other words with yellow, then the upper surface of the plate will be covered by a series of equally large and uniformly distributed triangles, which are tinted in eight colours owing to the various combinations of the individual colours. The following colour effects will be secured according as to the manner in which the several colours are individually superimposed:—

Red triangles *r*, yellow triangles *g*, blue triangles *b*, at points where two series of lines cross each other, green triangles *i*, orange-coloured triangles *o*, and violet triangles *k*; between these lines perfectly colourless triangles *w* and grey or black triangles which are produced by the crossing of all three lines.

Instead of printing with red, yellow, and blue, orange, green,

and violet may be used, whereby red, yellow, and blue will again appear at the points of intersection.

Without departing from the principle of the invention, the mosaic, provided it be very transparent, can also be applied upon the panchromatic layer or coating, which should always be done in cases where use is made of non-transparent supports—e.g., photographic papers. In such cases it is advisable to first of all apply to the photographic coating a thin transparent coating (gelatine, collodion, and the like), upon which the mosaic is impressed. The development of the picture can be effected right through this mosaic, which may however be avoided by stripping off and turning the coating prior to development.

The conversion of the negative into a positive, or of the positive into a negative, can easily be effected by this process, provided the coloured mosaic be placed upon a very slightly sensitive photographic coating—for example upon a print-out or copying layer—and if upon this coating there be applied a panchromatic emulsion adapted to be easily stripped. As the coating of print-out or copying emulsion is almost non-sensitive in comparison with the panchromatic emulsion little effect can be produced therein during the exposure to light. The panchromatic coating will be fixed as a negative if a positive be copied, thereupon the plate is exposed to the light in such a way that the negative appears on the printing-out or copying coating as a positive, whereupon the negative is stripped off and the positive present underneath is treated further—i.e., developed, toned and fixed or the like.

It may be pointed out that the colour of the chloride of silver coating (orange yellow) is a splendid substitute for the yellow filter usually required for such processes. Jan Szczepanik, 48, Valerie Strasse, Vienna.

**THREE-COLOUR CAMERAS.**—No. 22,310, 1906. This invention has for its object a camera in which a number of plates are exposed automatically in succession for predetermined periods. The plates with their colour-screens are carried in ordinary plate-holders which are inserted in grooves in a disc-shaped carrier pivoted at the rear end of the camera.

This disc is acted on by a spiral spring so that it tends to revolve, but it is normally held stationary by a bolt which engages with one or other of a number of catches on it. The bolt is operated periodically by a pin on a cam shaft driven by clockwork. In order to prevent shock when the disc is arrested by one of the catches striking against the bolt a brake whose rotary part is also actuated, the cam shaft may be provided to act on the disc just before the catch reaches the bolt.

The cam shaft has upon it a number of cams, one for each plate, and these cams are adjustably mounted on the shaft so that their relative positions can be varied to alter the time of the exposures. The cams act on levers which operate a spring bolt controlling the shutters. There is one shutter for each plate, and they have in them notches of different depths which engage with the bolts and are so arranged that when the bolt is withdrawn a short distance the first shutter falls but the others are retained in an elevated position, and when the bolt is further withdrawn a short distance the second shutter falls, the remainder being retained and so on, the bolt after each motion being prevented from returning by its nose being in contact with the side of one or other of the shutters.

The cam shaft performs a complete revolution for the three shutters, and each lever is provided with a spring tending to force it against its cam independently of the other levers, but these springs are weaker than that of the bolt, and the cams are of different diameters, so that as each cam comes successively into operation the bolt carries one of the other levers out of contact with its cam. John Snell Chenhall, Eggfrickland Road, Compton, Plymouth.

**CHINA-SURFACED METAL.**—No. 21,698, 1906. The object of the invention is to provide a substitute for opal or porcelain. The suggested material consists of a thin plate of steel, aluminium, or other suitable metal, or alloy, with a fused facing of vitreous china or other suitable substance, as a substitute for opal or porcelain; and of one of the celluloid class of preparations or other substitute for ivory. The plates intended as substitutes for opal or porcelain and paper may be rendered white in the

same manner as with opal or porcelain itself, or by the fused facing itself. The plates to be used in place of ivory may have an opaque facing of the celluloid or other substance, or have a semi-opaque facing upon a white ground, the facing in both cases being fixed to the metal after the manner of the fused facing. The necessary pitch of whiteness is obtained by an under surface of oxide of zinc directly by the fused facing, or otherwise. The "matt" surface required for painting on may be obtained by regulation of temperature in the facing, by sand-blast, or acid, and can be varied in texture to meet varying needs both with opal porcelain and the ivory substitutes. William Buist Pickers, 35, Agamemnon Road, West Hampstead, N.W.

**BLIND SHUTTERS.**—No. 1,468, 1907. The invention consists of a blind shutter of the type of that in Patent No. 16,593, 1905, with new adjustments to stop the movements of one or both curtains without the use of toothed wheels or similar butt mechanism. Instead, clutches are placed between a fixed abutment and roller-axle, these clutches having a certain amount of free or idle movement. Preferably these clutches consist of concentric discs provided with abutments and adapted to be rotated relatively to each other until their abutments come into contact with each other. The amount of rotation which can be imparted to the roller before its movement is stopped, depends on the number of discs placed between the roller and the fixed abutment. The extent of the rotation can, therefore, be regulated by regulating the number of clutch-discs used. Optische Anstalt Carl Goerz, Aktiengesellschaft, 44/46, Rhein Strasse, Friedenau, Berlin.

**FILM-DEVELOPMENT APPARATUS.**—No. 524, 1907. The apparatus consists of a closed vessel in the interior of which a spool of film can be fitted. A travelling carrier for the film roll is provided within the receptacle, and towards the end of the latter, remote from that to which the end of the film is secured, is disposed a roller or guide around which the film roll is drawn so as to unwind the film from the spool. The roll is drawn out to round the roller and back towards the starting point. The unwinding of the film is of course effected after the tank has been closed and the film can then be developed by successively passing in the necessary solutions through a suitable opening, a part of the process being on well-known lines. The tank

conveniently of such a shape that the film is unwound and drawn out round the roller in a horizontal direction, a support which is conveniently removable or which may be folded up out of the way being provided to enable the receptacle to be rocked or oscillated to ensure the solutions coming intimately in contact with the film.

In a developing machine of the present type it is desirable in unrolling the film it be laid upon its supports instead of being drawn across them, and it is also desirable if possible to dispense with a spacing apron such as has heretofore been employed where the film has been wound upon a reel. In the present invention, by providing separate transverse supports between which the film is extended by suitable means, the free end is fastened and the spool or roll then drawn over the support between them in such a way that it will be thoroughly exposed to the liquid in the container without liability of damage in the process of unrolling. Kodak Limited, Clerkenwell, London, E.C.

**ADDRESS WANTED.**—Hall and Co., 65, St. John Street, Coventry, ask us to say that a remittance and order for samples has been sent them from a Mr. E. Turner, giving an address at "Albion House, Burr Lane," but omitting to state the town. Mr. Turner is desired to write again.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Local Matting of Smooth Prints.

I give a dodge which I believe is quite new (writes Mr. R. Williams in "The Practical and Pictorial Photographer"). From the print which is made on smooth paper a tracing is made on tracing paper with white ink to show the exact portions which are to be matted. Now take a sheet of rough "sand" or "glass" paper, over this lay a sheet of carbon paper, and over this the tracing. Follow the white line with a blunt point, such as the end of a bone knitting needle. This gives a black line on the back of the sandpaper. Cut out along this line. The print, after fixing in alum, is hardened and dried. It is now steeped in tepid water, laid on a sheet of zinc face up. Over this is fitted the cut-out sandpaper sheet, and over this comes another zinc plate. The two metal plates with papers between are now put into an office screw-down copying press, and a good tight screw-down given. This forces the sandpaper unto the print in certain parts and keeps other parts smooth. Great care will be required in separating the sandpaper from the print. To reduce the shiny surface of a carbon print it may be rubbed with a trace of finely powdered pumice stone applied with the finger tip.

### Exposures with Two Light Filters in Combination.

Two filters were taken (says a writer in "The Photographic News"), and tested with a certain orthochromatic plate in order to find their multiplying factor, adopting the well-known method of exposing a plate in successive strips, and then noting which strip was of the same opacity as a negative properly exposed without any filter, the plates, of course, being developed together for the same length of time. The filters proved to be a six times and a three times. They were then placed together and another test made, the other conditions being unchanged. The multiplying factor proved to be 8. It would thus appear that where the colour of the two filters is alike, the depth only varying, and where the multiplying factors are not high, it is fairly safe to *add together* the factors for the two filters and use this as the factor for the combined filter. The greater the absorption of the first filter the less will a second filter increase the multiplying factor. The dirtier the yellow—that is, the more black there is in it—the higher will the factor be for the combined filter.

### High-Lights in Portraits.

When the professional retoucher is working up a negative (writes Mr. A. J. Anderson in "The Amateur Photographer") he follows a fixed scale of intensities in his high-lights. This is manifestly wrong, for the relative brilliancy of the high-lights on the various features depends on the texture of the skin, and this varies with different faces. A shiny skin will give stronger high-lights than one which has the bloom of the peach, for the shiny skin will reflect the light brilliantly, whereas the soft skin will diffuse much of the light, softening the high-lights, and lightening up the shading. The same holds good with regard to the various features; the skin of the nose is usually closer in texture and more tightly drawn than the skin of the other features, and consequently the high-light along the ridge of the nose is usually the strongest high-light, but this is not the invariable rule; the high-light on the forehead of a scientist, or the high-light on the clean-shaven face of a masterful soldier, might well prove the principal high-light in the picture.

### Copying Autochromes in the Camera.

An Autochrome positive (writes Mr. R. Child Bayley in "Photography") was fastened up over a hole cut in a board, and behind it was placed a mirror reflecting the cloudy sky. In order to secure as brilliant a result as possible, the space intervening between the Autochrome and the camera front was covered over with a focussing cloth, so that no light reached the lens except what had come through the Autochrome. The general arrangements, in fact, were the same as those employed in the ordinary way when making lantern slides by reduction, except that as it was not practicable at the moment to tip the whole apparatus up to face the sky, and as a white reflector tended to prolong the exposure unduly, a mirror at an angle of 45 deg. was employed instead. A preliminary trial of

the light showed that the Watkins meter turned towards the sky at the mirror itself, darkened to the standard tint in 45 sec., and by exposing a plate in strips, it was evident that an exposure of about half-an-hour would be correct. The lens was used at  $f/8$ , and the degree of reduction was such that the original 7 in. wide was reduced to a width of  $3\frac{1}{2}$  in.

## New Books.

"Photograms of the Year, 1907." (London: Dawbarn and Ward, Ltd.). 2s. nett and 3s. nett

We welcome this annual record of pictorial photography because of its far-reaching catholicity. Nowhere else is it possible to find, between one pair of covers, such an exhaustive selection of the work of all civilized countries. Our own journals give us, more or less successfully, and in dribbles, a liberal reproduction of the two London public shows; but those papers do but repeat each other after all. He who takes them all gets no wider idea of the year's work than he who sees but one. "Photograms" gives about 200 pictures, of which fifty only, roughly speaking, are from the "Royal" and "Salon," and therefore already known to the public. The printing of the plates is, for the most part, highly creditable, and much above the average of the photographic papers and the Royal Photographic Society's catalogue. Where it fails is in those sheets that have received faint grey and coloured inks. On the whole, a black ink is the most just to the tones of a picture, even if the original be in colour.

Mr. H. Snowden Ward leads off the letterpress with graceful compliments to his predecessor in criticism, Mr. A. C. R. Carter, and modestly assumes that retiring gentleman's duties. The first noticeable result of this change is a satisfying absence of bias and prejudice in all references to the rival exhibitions of Regent Street and Pall Mall, and no gross misstatements, such as we were constrained to point out last year.

Mr. Ward's idea of an art-critic's obligations are not exactly coincident with those recently discussed by art critics themselves in "The Academy," where it appeared that the critic should be the artist's exponent to the public. Mr. Ward considers that his duties lie in the way of being the mentor of the artist. In his case that course is no doubt the most expedient, since the majority of photographers are more in want of a gentle pilot than of a prophetic showman. He goes so far as to raise a new question for universal discussion: "Are photographers artists?" and answers it "with a distinct, emphatic negative as regards the immense majority." Indeed, his article may be called a tirade to the demerit of amateur photography generally; but in particular he is timorous of treading on a corn here or there. This amiable tolerance of the individual is perhaps a little multiplying to his broad fist-swinging when general matters are in question. Yet where a cap will fit it will no doubt be worn, and that without chafing, and it may be that Mr. Snowden Ward, in his wisdom, has chosen the more excellent way.

A distinguishing and interesting feature of "Photograms of the Year" is the various criticisms of the year's work abroad, contributed by men of standing in the respective countries. These contributions are perhaps a thought less light and airy than those of the last issue, but one or two are excellent reading even to a layman. M. Demachy's easy English is always a delight. He laments the "negative" event of the absence of the Photo-Club Salon this year, prophesying its appearance bi-annually in the future. He deals very largely with what he calls the trichrome plates, a nice distinction from "autochrome," and he shows very cleverly how the numerous tries at colour transparencies by no means invariably deserve the prefix auto. With truth and wisdom he says: "We must resign ourselves to the inevitable atrocities that the over-confident amateur is going to thrust upon us. I have already met with a certain number of eyesores of that description, in comparison with which the coloured advertisements in the sixpenny magazines are soothing." Speaking of oil-printing, he informs us that the Paris Photo-Club Committee intends to organise for next February a very select one-process show for oils, and he hopes that England—the birthplace of Rawlins—will send something good.

F. Mathies-Masuren, writing of Germany and Austria, records a diminished interest in German art-photography, attributable perhaps to the high standard maintained by judges, and on account of which

many amateurs find their work inadequate and their labour in vain. After all, this is a good fault on the part of the judges. In this country we can testify to the high quality of what does succeed in passing the juries, and there seems to be enough of that. Per contra we are informed that in Austria there is perhaps not so much advance on previous technical and artistic achievement, but an eager and united activity, and "a lively interest in the welfare and good fame of their clubs." This is somewhat as it is in England. Yet of what avail is club-life if technical and artistic achievement does not advance? Herr Mathies-Masuren further states that "the amateur in Germany cannot hold his own against the foreigner; but the very reverse may be asserted of the professional."

Spain, according to M. Mendez Leon, appears to be a trifle backward, since it is in the enthusiastic stereoscopic stage still. At an exhibition of the Royal Photographic Society of Madrid, there were nearly 2,000 examples, 600 of which were stereographs! It appears, too, that competitors for the Diploma of Honour forfeit all their prints, which remain the property of the organisers of the competition. The result is that all amateurs who value their prints above the Diploma of Honour keep them and forego the competition. "Oh, what a happy land is England!"

We are sorry to miss Mr. Roland Rood's sprightly article upon America. That upon the Western States, by F. J. Clute, and that by Sidney Carter upon Canada are somewhat categorical, and, therefore, of not such interest as a general article would be to readers who do not know the work of individuals upon the other side of the globe. The most stirring thing in the Western States is certainly the fact that a gentleman in Washington is engaged upon a work of twenty volumes upon North American Indians. The price is to be £600 a set, and only 250 sets will be done, so we are glad to be able to make this early announcement to our readers, who, we feel sure, would be sorry to let such an opportunity slip.

Edwin J. Welch treats of Australia in an article of excellent reading and of amusing style. The prevailing characteristic of Australian photography is "grooviness," he says, adding that the British and American publications do not convey the impression that Australia possesses a monopoly of it. In professional matters he laments the "cutting rates": "The advertising columns of the daily papers carry the announcements in glaring type that two photographers in one of the States are offering 'One dozen cabinets in the latest style of art, superbly mounted and finished, and one beautiful enlargement on bromide paper, 18 in. by 22 in., handsomely framed in a costly moulding, for the sum of 7s. 6d.'" He continues: "The studios referred to are in the first flight, and I am constrained to acknowledge without any reservation that the work turned out at each place is really good." Mr. Welch has some diverting remarks upon the lady amateur, of which, he says, there are plenty, "all more or less lovely and collectively charming, but extremely sensitive as to criticism."

We cannot close this review without highly recommending the book as a worthy archive for the photographer's library and a thing of beauty and a joy for ever for the visitors to his drawing-room; hence his necessity for two copies.

"The Burlington Art Miniatures of the World's Great Masterpieces." The Fine Art Publishing Company, Limited, London, E.C.

We have received the first number of this publication containing ten samples from the King's private collection of paintings. The prints are in the Mezzogravure process, about 5½ in. by 4 in., and are contained in a well designed and attractive little box-form portfolio. The numbers are to be issued fortnightly at the price of 1s. 6d. each, and the series is to be completed in 20 number with 200 prints, every subscriber to the whole set receiving free of cost a substantial cabinet holder for the complete series. As regards the reproductions we can only describe them as excellent. The first number includes a series of six portraits by Lawrence, Van Dyck, Holbein, Rembrandt, Gainsborough, Rubens, and Delaroche that form very suggestive studies to the portrait photographer. Succeeding numbers will include the Wallace Collection, the National Gallery, the Louvre, the Luxembourg, the Tate Gallery, the Walker Art Gallery, and numerous other British, American, and Continental Galleries of world-wide repute, and the complete collection of 200 pictures should therefore contain a large proportion of subjects of value to photographers. We should strongly recommend all desirous of enlarging their ac-

quaintance with pictorial masterpieces to secure this collection of reproductions. The whole series will only cost 30s., and the example are so good as to be worth collecting for their own sake, quite apart from the practical value that they should possess for pictorially inclined photographers.

## Dew Apparatus, &c.

The "Memo" Stylo. Made by Mabie Todd and Co., 79 and 80, High Holborn, London, W.C.

To the outdoor photographer this conveniently small stylograph pen should be a most useful companion since its size allows of its being carried in the waistcoat pocket protected from the risk of loss to which the longer fountain pen is exposed. The "Memo Stylo

writes with the smoothness which the makers have led one to expect in the "Swan" pens, and is a most satisfactory substitute for the pocket pencil. Its price in black, mottled, or red vulcanite is 2s. 6d. The illustration shows its actual size.

## CATALOGUES AND TRADE NOTICES.

**SOME HINTS ON ENLARGING.**—Under this title a very attractive booklet of thirty-two pages has been prepared by Messrs. Houghtons Ltd., 88-89, High Holborn, W.C. It supplies quite sufficient information to enable a beginner to commence enlarging work, and describes a variety of the most convenient apparatus, including a series of lanterns which permit of the worker's own camera being used instead of a more expensive complete enlarging lantern. Messrs. Houghtons offer single copies of the list to our professional and amateur readers; dealers should apply to them as to obtaining a supply for the counter. The bold coloured cover of the booklet should be a valuable means of drawing attention automatically to enlarging facilities.

**CANVASSER FINED.**—Job Lewis, canvasser, of Seymour Street, Euston, was charged, on remand, with stealing twenty-five photographs, of the value of £1 5s., the property of Isaac Agulay. The prosecutor said that he was ill in bed, and prisoner offered to fetch a doctor. He went, and had not been seen since. In passing from the bedroom he could have gone through the studio, and could have had access to the photographs, which were missed the same afternoon. Mr. d'Eyncourt fined prisoner 20s. and 10s. costs.

**MUNICIPAL PHOTOGRAPHY.**—The following letter, over the signature of George H. Cowlshaw, appears in the "Sheffield Daily Telegraph": "During the process of demolition of old Sheffield buildings for street improvement, I often regret that our corporation have no official photographer, so that pictures should be preserved of old buildings of interest. Many now are lost to sight which are to memory dear. A lot of old shops of interest in Westbar and Shalesmoor, an old nail shop in Pond Street, the old baker's shop in Baker's Hill where we used to get the old coloured spice animals, and lots of old places could be named, some of them with very fine moulded doorways. I hope some abler pen than mine will take the matter up, and let something be done before it is too late."

**ACETYLENE PORTRAIT LIGHT.**—According to a report in the "Kent Argus," the acetylene light has been successfully installed in the studio of Mr. Louis G. Carpenter, of 88, High Street, Ramsgate. The arrangements have been carried out by Messrs. Bray, the well-known firm of gas implement makers. The installation consists of thirty burners, of 200 candle-power each, giving a grand total of 6,000 candles. The light is not in the least trying to the eyes, giving a soft yellowy light, and can be moved in any direction, according to the photographer's wish, and has a distinct advantage over the electric variety, with its blue penetrating light. A number of photographs taken with the new apparatus thoroughly convinces one that it does all that it is claimed for it, the details being brought out magnificently, notably if the sitter is wearing white.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 1.

Amateur Photographic Club. "Amateur Photographer 1907 Prize Slides."  
London Photographic Association. "Passe-Partout Mounting." Jas. Milne.  
Co-operative Society Camera Club. "Enlarged Negatives on Rotograph Negative Paper."

MONDAY, NOVEMBER 4.

South London Photographic Society. "Figure Study." E. T. Holding.  
London Photographic Society. "Tabloid Chemicals." Messrs. Burroughs, Wellcome & Co.  
London Photographic Society. "Colouring of Lantern Slides." F. E. Fearnside.  
London and Forest Hill Photographic Society. "Retouching." W. Michel.  
London Photographic Society. "Isochromatic Photography with the Wellington Iso Plates." H. Wade.  
Cambridge Camera Club. "Enlarged Negatives on Rotograph Negative Paper."

TUESDAY, NOVEMBER 5.

London Photographic Society. "Autochrome Plates." Demonstrated. T. K. Grant, F.R.P.S.  
London Photographic Society. "Photography: Its Possibilities, from a Popular rather than a Technical Point of View." L. A. Edmonds.  
Hill and District Camera Club. "Rotary Carbograph Paper." Rotary Society and District Photographic Association. "An Evening with Pictures." W. Baerhaw.  
London Photographic Society. Council Meeting.  
London Photographic Society. "Colour Photography," including the "Lumière Autochrome Process." H. Denison and F. W. Branson.  
Manchester Amateur Photographic Society. Members' Slides.  
London Photographic Society. "Photographic Chemicals."

WEDNESDAY, NOVEMBER 6.

London Photographic Club. "Bromide Printing and Toning." W. H. McLaughlan.  
London Polytechnic Photographic Society. "Rotary Carbograph Paper." Rotary Photographic Co.  
London Camera Club. "Flashlight Portraits." E. C. Alcock.  
London Camera Club. "Kallitype." J. M. Sellers.  
London Camera Club. "Flower Photography." W. H. Atkinson.  
London Suburban Photographic Society. "Stories and Glories of Westminster Abbey." E. W. Harvey Piper.  
London Technical College Photographic Society. "Iford Lantern Plates." Algernon Brooker.  
London Photographic Society. "The Reproduction of the Photograph by the Half-Tone Process." T. Cuthbert Day, F.R.S.  
London Amateur Photographic Society. "Holland and Normandy." Rev. Henry W. Dick.  
London Middlesex Photographic Society. Lantern Slide and Print Competitions.  
E.R. Mechanics' Institute. "Photographic Chemicals."  
London Photographic Club. "Mounting." W. Brush.

THURSDAY, NOVEMBER 7.

London Amateur Photographic Association. "Genre and Figure Studies." T. Lee Syms.  
London and District Camera Club. "Rotary Carbograph Paper." Rotary Photographic Co.  
London Photographic Association. "Pigment Printing." A. W. Hill.  
London, Farsley and Calverley District Photographic Society. "Mounts and Mounting." L. Dickinson.  
London Photographic Society. "Bruges." The President.  
London Photographic Society. "Practical Lantern Slide Making." R. H. Lawton.  
London Camera Club. Lantern Evening.  
London Club. Smoking Concert.  
London Photographic Society. "Rotary Carbograph Paper."  
London and Institute Camera Club. "Iford Lantern Plates." Algernon Brooker.  
Manchester Amateur Photographic Society. "In a Tyrolean Valley." James Shaw.  
London Photographic Society. "Time Development." Philip Whitehouse.

WISHAW PHOTOGRAPHIC ASSOCIATION.—The sixth annual exhibition of this society will be held from December 31, 1907, to January 4, 1908, inclusive. There will be seven open classes, including a novice class, and one also for associates of the Scottish Photographic Federation. Plate and bronze salvers will be awarded in each class. The judges will be Dr. Richmond and R. Clouston Young, R.V.S. The closing date for entries will be December 18, and the last day for receiving pictures December 25. Entry forms and further information may be had from the secretary, R. Telfer, 138, Glasgow Road, Wishaw, N.B.

THE BRISTOL PHOTOGRAPHIC CLUB.—The hon. secretary, Mr. Geo. Masonsmith, opened the winter session with a racy account of a stor trip in the southern counties, illustrated by a large number fine lantern slides.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—At a meeting, held on October 23, Mr. Mackinney in the chair, Mr. W. Green, of John J. Griffin and Sons, Limited, gave a demonstration of "The Leading Principles in Velox Manipulation."

SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.—Lecturing last week, Mr. E. T. Holding dealt with "Figure Work," and gave quite a

number of practical hints as to how it is done. Photographic technique, he pointed out, may be easily mastered by anyone, though the sense of the beautiful necessary to the pictorial photographer must be innate, and cannot be acquired. The successful amateur photographer was, in fact, the enthusiast who can see beauty, and, without the technical skill to draw it himself, resorts to the lens to draw it for him. He would recommend the study of modern pictures rather than of old masters, for pictorial photography was essentially modern, and modern art was the mother of it. This study should be undertaken, not for the purpose of imitation, but for the purpose of suggestion. His advice was to create, not to imitate.

SOUTHAMPTON CAMERA CLUB.—On Monday last, October 28, Mr. E. Seymour lectured on "Floral Photography."

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At last Monday's elementary meeting "Tabloid Development" was demonstrated by the hon. secretary, Mr. Gideon Clark, who stated that he had used the Burroughs, Wellcome products in his own photographic work for many years past with every satisfaction. A snapshot, which received only 1/50 sec. at f/11 on the same day, was successfully developed by "tabloid" pyro-soda, a severe test, showing the efficacy of freshly-made solution. Some lantern slides, both of black and warm tones, were also made with excellent results.

## Commercial & Legal Intelligence.

AGENT'S BANKRUPTCY.—James Stroud Nunn, formerly dealer in photographic materials and manufacturers' agent, 11, Queen Victoria Street, E.C., attended before Mr. Registrar Brougham, sitting at the London Bankruptcy Court, on October 25, for his public examination, upon a statement of affairs showing liabilities £893 3s. 11d., of which £775 3s. 11d. were returned as expected to rank, and no tangible assets. Mr. G. W. Chapman attended as Official Receiver. It appeared that the debtor began business as a dealer in photographic materials and manufacturers' agent in July, 1906, and traded under the style of James S. Nunn and Co., at 11, Queen Victoria Street, E.C. Another person agreed to finance the business to the extent of £1,000 on the security of future book debts and the stock to be acquired. It was also understood that the business should subsequently be formed into a company, and, as soon as he began to draw against the £1,000, the question of the promotion became pressing. In January the company—called James S. Nunn and Co., Limited—was formed, with a nominal capital of £4,000, divided into £1 shares, of which 2,000 were allotted to his wife as his nominee. He became chairman and manager of the company at a salary of £250 a year, but up to the present he had received no remuneration. The only part of the business that prospered was the photographic branch, and, as capital was required to develop that department, Satino, Limited, was formed, in February, with a nominal capital of £500 in £1 shares, to acquire that department. James S. Nunn and Co., Limited, were paid £328, in £1 shares, of Satino, Limited, and a debenture of £500, representing the absolute value of the stock, he handed over to Satino, Limited. The debtor became a director of the latter company at a salary of £2 a week. The examination was ordered to be concluded.

NOTICE OF DISSOLUTION.—The firm of J. Lizars, Opticians, 251, High Holborn, London, of which Robert Ballantine, Arthur Ballantine, Hew Ballantine, and A. H. Bellefontaine were the partners, has been dissolved by the retiral of the said A. H. Bellefontaine from the firm. The business will be carried on as formerly by the remaining partners at the same address, and under the same name.

CHARGE AGAINST A PHOTOGRAPHER.—At the West London Police Court last week, Henry Spencer, 53, described as a photographer, of Laurel Gardens, Hanwell, and Arthur Joyce, 40, a canvasser, of Marlborough Road, Walford, were charged on remand with being concerned with another man not in custody, in stealing and receiving sixteen £5 Bank of England notes, belonging to John Wake, of 268, Latimer Road, Notting Hill. Mr. Ley prosecuted for the Treasury, and Mr. Pierron defended Spencer. It was stated at the previous hearing that Mr. Wake made the acquaintance of Spencer in December, 1906, through the latter advertising for some

one to put money into a cycle company (British Cycle Manufacturing Company), and he (Wake) alleged that the company into which he did put some money was a bogus one. Joyce was acting as Spencer's clerk. In September Mr. Wake was living at 25A, Eynham Road, Hammersmith, and he alleged that a roll of bank notes was stolen from his portmanteau. Detective-sergeant Burrell stated that on arresting the defendants he was given a statement by Joyce, who declared that at Spencer's instigation he cashed the notes at different places—chiefly post offices—in Gravesend, Chatham, and Rochester, and the sergeant further stated that in the possession of Spencer he found the counterfoils of two postal orders, and on the backs of some of the notes (which had since returned to the bank) were the numbers of the postal orders. Evidence was given by Horace Joyce, the twelve-year-old son of the prisoner Joyce, to the effect that they used to live at Windmill Street, Gravesend, and that last September Spencer called at their house and got the witness to show him the way to the post office, where he (the witness) saw him purchase some postal orders. Among other witnesses was a clerk from a bank in Chatham, who was called to prove that one of the bank notes said to have been cashed by Joyce with a tradesman was paid into the latter's account. The witness produced a copy of the entry in the bank's books. Mr. Ley thereupon observed that no doubt such evidence might be objected to as inadmissible. By an Act of Parliament (continued Mr. Ley) which was specially passed for the benefit of bankers, it was granted as a privilege to banks that a photographic reproduction of an entry would be sufficient as evidence, but it was a growing practice among some banks to furnish a mere copy of entries. Mr. Lane, K.C., agreed and refused to admit the witness's evidence, observing that he would be obliged to attend the court a second time so as to furnish proper evidence. The accused were again remanded.

**CANVASSING FRAUDS AT CHISLEHURST.**—At the Bromley Petty Sessions last week Joseph Lemoine, 28, of West Kilburn, canvasser, was charged on remand with attempting to obtain various sums from servant girls by means of a worthless photo-coupon, at Walpole, Manor Park, Chislehurst. Particulars of the charge appeared in the "B.J." for October 18. Helen Anderson, a domestic servant at "Nizels," Kemnal Road, Chislehurst, said on Saturday, October 5, the prisoner came to the house and said he was canvassing for Lintotts in Bond Street. He also stated that they had opened a shop at 130, High Street, Bromley, and then said he would do some cabinet photographs for witness like those produced at the rate of 6s. 6d. per half dozen, with a large one given in. He filled in the coupon produced, and witness then gave him 5s. 6d. She did not have her photograph taken, but on Monday afternoon, October 7, witness and two of the other girls at "Nizels" went to 130, High Street, Bromley, the business premises of Mr. Harman. They saw there Mr. Harman's assistant, Mr. Dudman, who said that nobody was canvassing for his employer. On Saturday night, October 12, she attended at the Chislehurst Police Station, and there identified the prisoner from amongst eleven other men as the man who had agreed to take her photograph. Annie Turrell, another domestic servant at "Nizels," Chislehurst, the residence of Mr. Travers Hawes, J.P., said on October 5 the prisoner called at the house and offered to take her photograph on terms similar to those mentioned by the previous witness. She also went to Bromley on the following Monday and then discovered that the prisoner's story was untrue. Detective-sergeant White said at 3 p.m. on Tuesday, October 15, he went to 118, New Bond Street, occupied by August Walker, a photographer. He examined two rooms at the top of the house and found that they were not occupied by Messrs. Lintott. There was no such firm as Messrs. Lintott carrying on business as photographers in New Bond Street at the present time. Prisoner was cautioned in the usual way. He elected to be dealt with summarily and pleaded guilty. In a statement handed in to the Bench for their consideration he said he had been induced to act in this manner in consequence of family affliction. He had never been in trouble before and asked for leniency for the sake of his wife and children. In future he would lead a straightforward life. The Chairman said the Bench had very carefully considered what course to take in this case. It was impossible, for them to shut their eyes to the fact that these offences were not committed on the spur of the moment. It was a most carefully

planned trap to get people to advance money to him. At the same time they took into consideration the fact that the prisoner had clean sheet so far, otherwise the Bench would have had to do far more seriously with him. The order of the Bench was that should go to prison for one month in the second division.

**ARTISTIC PHOTOGRAPHIC COMPANY, LIMITED, LONDON, W.**—Registered October 14, for £1,000 seven per cent. debentures, of £2,000 authorised; no trustees; charged on the business assets present and future.

**UP TO THE CANVASSING FRAUD.**—In the Stockton County Court last week the Middlesbrough Fine Art Company sued William Colpitts for 10s. 6d. Joseph Stones' plaintiff's agent, said defendant gave an order for an enlargement, and the 10s. 6d. was the frame. Defendant said the photo-enlargement was free advertisement, and, thinking that the trick would be to get price of the enlargement in the frame, he made plaintiff endorse order as a free enlargement only. The photograph was not delivered, but was left at a neighbour's house. His Honour told defendant plaintiff must not do that kind of thing, and gave judgment for defendant with costs.

## News and Notes.

**THE TICKA POSTCARD COMPETITION.**—An enormous number of entries were received for the competition inaugurated by Messrs. Houghtons Limited in connection with the "Ticka" camera. Humorous postcards, designed by Mr. Charles Harrison, were issued through dealers and others, and the public invited to suggest titles for them. The competition closed on September 30, and a cheque for two guineas for the best title for each picture has been forwarded to the following competitors: A. H. Tapper, Ealing; W. L. F. Wastell, South Woodford, Essex; M. L. Carter, Tuf Park, N.; Miss S. Browne, Windsor; Major H. Blyth, Tower Merioneth; E. V. P. Simpson, Manchester; Harry Cross, Halifax; A. J. Freeman, Thatcham, Berks; Ernest Stansfield, Rotherham; D. Kennedy, Manchester University; A. Porrett, Harrow; A. B. Oddie, Norwich.

**THE AUTOCHROME DEMONSTRATION AT THE R.P.S.**—Mr. McIntosh, the secretary of the Royal Photographic Society, writes: "I expect a very large attendance at the demonstration of the Autochrome process, to be given by Mr. Thos. K. Grant on Tuesday, November 5. I shall take it as a favour if you will announce your readers that members of the society only can be admitted to the meeting-room before 8.5 p.m. After that time visitors will be admitted as far as the accommodation will permit. Your readers may be interested to know that the attendance at the New Gallery during the annual exhibition has been much in advance of all previous years. The numbers for 1905 were 12,196, for 1906 15,229, for 1907 22,240. These are exclusive of the attendances at the society's private view, and press view, which would raise the total for 1907 to 24,000."

**ILLINGWORTH CHRISTMAS POSTCARDS.**—Suitably inscribed postcards in all the grades of their paper, "bromide," "Zigo" self-toning, "Zigas," are issued by Messrs. Thomas Illingworth and Co. in shilling packets of twelve cards.

**AUTOCHROMES OF NATURE SUBJECTS.**—At the Blenheim Club on Thursday last week, a numerous company of members and friends assembled to hear Mr. Martin Duncan describe his experience with the use of Autochrome plates in nature photography. Mr. Duncan commenced by saying that, although he had worked nearly a dozen years in the colour process, it was not until he tried the Lumière method that he was able to obtain the delicacy and fidelity of colouring which were a necessity to the naturalist-photographer. He had therefore lost no time in applying the new Autochrome plates to the photography of insects and other subjects. He believed he was the first to employ the plates for this purpose. Mr. Duncan then explained the theory of the Autochrome and Warner-Powrie processes, and exhibited a negative spectrum, taken on the latter process, which appeared to be as good an example of its kind as that shown at the recent exhibition of the Society of Colour Photographers. The lecturer then proceeded to exhibit a series of Autochrome records, recording many striking examples of colour mimicry in animal

dition to a number of colour photographs of such living subjects as caterpillars, moles, and butterflies. The exposures had usually run into fifteen to thirty seconds, but by choosing a time when the animals were torpid in sleep, Mr. Martin Duncan had been highly successful.

**A WEEKLY CONVERSAZIONE AT GRIFFIN'S.**—Messrs. John J. Griffin and Sons announce that they have now arranged for a conversazione to be held at their Kingsway House, every Thursday evening, from 7 to 9. Admission is, of course, free to all who are interested in photographic matters. The following is the programme, which will largely varied from time to time:—(1) Exhibition of micro-photographs and other specimens in real colour photography on Autochrome plates, accompanied by lecturette. (2) Demonstration with the oil-gum process and lecturette. (3) Exhibition of new "Autokon" enlarger. (4) Exhibition of photographs illustrating Mr. Howard Farmer's new method of regulating tone values.

**THE LATE MR. A. L. HENDERSON'S WILL.**—Mr. Alexander Lamont Henderson, of 277, Lewisham High Road, S.E., who died on July 5 at Bad Nauheim, Germany, left estate of the gross value of £4,492 5s. 9d., of which the net personalty has been sworn at £1,156 5s. 10d. The testator left £2,000 for the purchase of an annuity on the joint lives and the life of the survivor of his daughter (Mrs. Thomasina Inglis Grey) and her son (Wm. Henderson Grey), to the latter of whom he left his photographic apparatus; and he bequeathed

A sum sufficient to produce an annual income of between £5 and £10 upon trust to found a prize to be awarded annually by the London and Provincial Photographic Association, of Tudor Street, E.C., whom failing, by the Royal Photographic Society, for the most useful discovery in, or essay upon, photographic chemistry in the year.

Four ceramic frames of photographs, as to one each to the London and Provincial Photographic Association, the Royal Photographic Society, the Edinburgh Photographic Society, and the Photographic Society of Ireland.

His lantern slides and catalogued exhibits (but not Royal photographs taken for the late Queen Victoria, which it is forbidden to publish) to the Church Army.

A replica in terra-cotta of his bust by Albert Toft to the London and Provincial Photographic Association.

He left the pin presented to him by the Emperor of Austria, his presentation chemical balance, and his bust by Albert Toft to his daughter, Thomasina Inglis Grey, to devolve as heirlooms; and, in respect to several other bequests, he left his real estate in Scotland and elsewhere to Mrs. Grey for life, with remainder to her son, William Henderson Grey, and his personal estate to her absolutely.

**"VELOX" COMPETITIONS.**—The prize-winner in the September competition are announced by Messrs. Griffin to be as follows:—First prize, £2 2s., E. Vanandel, Finchley, N.; second prize, £1 1s., Thomas Stevenson, Addlestone. Consolation prizes of 5s., J. A. Pitchforth, Addersfield; W. Wood, Hamilton, N.B.; W. H. Thompson, Northampton; E. Henstall (Miss), Nottingham; Thomas Chester, Burnley; Beaumont, Newcastle-on-Tyne; W. Clegg, Burnley; Miss M. Rholomew, Beckenham; B. Perks, Teddington; W. H. Withey, London; F. Foster, Scarborough; L. G. Castle, Cheam, Surrey. It should be noted that the competition is strictly for those who have never won a prize before.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—The annual dinner took place on Thursday, the 24th, at the Hotel Boulogne, when T. E. Freshwater presiding, after which a programme of excellent music was greatly enjoyed. The toast of "The King and the Royal Family" fell to the lot of the chairman, as did also that of "The L. and P." "The Visitors" was given by Mr. Benson, and replied to by Messrs. Wate and Sharp; whilst to Mr. Ernest Human (the hon. secretary and recorder) fell "The Press," and to Mr. S. Herbert Fry that of "The Chairman."

**CONVASSER'S QUALIFICATIONS.**—A long-delayed charge of wife snatching came up for disposal at the Dundee Police Court last week. May 26 last John McGregor, canvasser, assaulted his wife by pressing her throat and pushing her through the window. He was found, and has since been working as a photographer's canvasser in Perth.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO. 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photomans at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- B. A. Jones, 1, Academy Street, Warrington. Two Photographs of the Laying of the Corner Stones of Orford New Church.
- J. Hodson, 153, South Parade, Cleckheaton, Yorks. Photograph. Snapshot of Halifax Tram Conductor's Funeral, killed in the Sowerby Tram Accident on October 15.
- Mrs. M. E. A. Powles, St. Oswald's, Griffe, N.B. Photograph entitled: "Our Lady of America." Photograph entitled: "Sunshine, Wind and Water."
- S. J. Porter, 21, Victoria Parade, Torquay. Coloured Photograph entitled: "Off to the Baby Show."

**PROCESS WORK.**—I want to become acquainted with reproduction work for magazines and books, but have not the vaguest idea how it is done. Could you recommend a book giving elementary information?—REPRODUCTION.

Better get "Photo-mechanical Processes," by W. T. Wilkinson (Hampton and Co., 4s.).

**BACKGROUNDS.**—1. Would you oblige by giving instructions how to mix paint for flatted oil background scenic; also for distemper (dark grey) plain. 2. What is the most economical way to make gold chloride for sulphocyanide bath?—J. J.

1. Full working instructions for making backgrounds were given on page 82 of the issue for February 1, and on page 155 of that of March 1, to which we must refer you. 2. Place half a sovereign in a porcelain vessel and pour on it half a dram of pure nitric acid mixed with two and a half drams of pure hydrochloric acid and three drams of water, and heat, but do not make it boil. If this does not dissolve the whole of the gold, more of the acid mixture must be used. Then evaporate to dryness on a water bath. Unless you employ a large quantity of the chloride of gold, and take great care not to waste any in the manufacture, you will find it far more economical to purchase it.

**B. DOS SANTOS LEITAS.**—Instructions as to the process have appeared in our issues of September 15, 22, and 29. Further articles will appear, and we shall deal more fully with the process when the plates are on the market, which will be in a few months' time.

**COLOUR CAMERA.**—In König and Wall on "Photography in Natural Colours" a clockwork camera made by Perscheid, of Berlin, is mentioned. Could you inform me whence I could obtain further particulars of this camera, which is designed to automatically change the plates, screens, etc.?—GEORGE A. KNAPP.

Full details could no doubt be obtained from the makers, MESSRS. Hoh and Hahne, of Leipzig.

**HANDS AND WIGDER.**—The Tress Co., 42, Oxford Street, London, W. We cannot say as to the bromide papers.

**ARTIFICIAL LIGHT.**—Would you kindly give me some information on the following subject:—1. I have a room 14 ft. 6 in. by 11 ft. which I am desirous of fitting up as a studio with artificial light. Is the room large enough? I cannot get electricity, so would have to use incandescent light. How many burners would be required to take successful full-length portraits by? 2. Is it possible to obtain as soft effects with this as with daylight?—J. H. W.

1. The room is really too short to take satisfactory full-length portraits in. It will do very well for three-quarter lengths, or bust portraits. Ten or a dozen burners will yield a fair light. The more there are, the shorter will be the exposure required. The exposure depends upon the number of burners and the distance they are from the sitter. 2. Yes, if the light is judiciously

arranged, as see the article on the present exhibition at our offices.

**COPYRIGHT QUERY.**—A few months ago I photographed a bookstall by consent of the clerk in charge, after which I sold to the employees thirty-four copies at 1s. each. Since then the firm have published the picture in leaflet form, and issued some thousands as an advertisement. Will you kindly inform me if I have any claim upon them, as it was not sold for publication, and my name was not printed on the leaflet? If I copyright now can I stop the distribution?—H. J. W. BRAY.

If you received nothing for taking the photograph the copyright in it belongs to you. If you register the copyright in it now you can restrain the issue of further copies.

**J. A. WOOD.**—You can get enamel metal developing dishes up to 24 x 19 in. from any large dealer, like Fallowfield, Houghton, Kodak, or Marion. See these firms' lists. We should advise you not to use an enamel-coated dish for gold toning.

**G. DAVENHAM.**—1. We cannot say. The book is of American origin, and the blotter also, we expect. Why not try the result of a reply postcard to the author, care of his publishers, or apply to an American supply house such as Geo. Murphy Inc., 57, East Ninth Street, New York?

**POSTCARD OFFENCE.**—Some little time ago I was out with my camera and I took the enclosed photograph. As you see the couple in the foreground are arm in arm. By way of a joke I spotted the negative, and it appears as though the lady had her arm around the gent. On Saturday last, the 19th inst., this was published as a postcard view. On the Monday following the lady came round demanding me to destroy the cards and not publish any more. At first I did not admit that I had put the arm on, but asked her if the cards were published without the arm would there be any objection. She replied that there would be no objection whatever, providing the arm was taken away. This I promised in the long run to do. The next day the gentleman came round with the same argument and demanding an apology. I asked him the same question as the lady, and he replied that he also had no objection to it being published without the arm. Then I took him and showed him the negative in the printing frame and pointed out that I had already taken the arm out. I also gave him a note expressing my sorrow and regret that I had published it in that manner and promised him (in writing) not to print any more with the arm on. This apology, he said, was to show the parents of the lady that the plate had been faked up in that manner.

I thought then that was the end of it, but now he comes round demanding the negative to be broken. He says he has been to a solicitor, and he gives me one day's notice to break the negative. Now, may I ask, what is my position? Can they stop me from publishing the cards (with the arm removed, of course)? Have I brought myself within the reach of the law in any way?

I have done all they asked of me, short of breaking the negative, and as they both said there was no objection to it being printed as originally taken.—H. S.

As in the first instance you faked the negative in the way you did it is not surprising that the parties felt much annoyed when the prints were published. Since it held them up to ridicule by those who knew them. Pictures holding private persons up to ridicule are libellous, and the ones sent might, under the circumstances, possibly be held as such in a court of law. We think your best way will be to do as the parties demand—destroy the negative. To say the least of it, it was bad taste on your part to take advantage of what you say was only a joke.

**MARIOTYPE PROCESS.**—I shall esteem it a great favour if you will inform me where I can procure a pamphlet or book, or any information upon the Mariotype process. If such process has been published in the JOURNAL perhaps you could give me the date? It has occurred to me that in conjunction with the carbon process (with which it is somewhat similar in some respects) it might be used beneficially, especially Mariotype, by pressure.—J. T. EASTON.

M. A. Marion's paper on the Mariotype process, read before the Photographic Society, will be found on page 242 of our volume for 1873. No other details of the working of the processes have

been published since, that we are aware of. The processes now came into practical use.

**SAFE-LIGHT FORMULA.**—On page 803, "B.J.," Mr. Payne gives formula for a green safe-light solution for Autochrome plates and concludes by saying, "Dilute this solution with 25 parts of water." If some error has not crept in, it would be interesting to know why the formula should not read—water (or 325 parts).—R. P. G.

Mr. Payne writes:—"It was my intention that the instructions should have been read as follows: 'Dilute this (bulk) solution with 25 parts (of equal bulk) of water.' It would have been more clear if I had written: 'Dilute one part of this solution with 25 parts of water.'"

**RETOUCHER.**—You have a very fine, close stipple, but far too mechanical, and applied in exactly the same manner to old and young. Be as fine and delicate as you please for women and children, but for men, young and old, vary your touch. Show more grain, but let it be softly blended, and not picked out in hard regularity. With very old faces, be exceedingly light on your lead, and do not work too closely. Half the character has been taken out of the bearded man's forehead with over-working. Your edges of light and shade in each study require softening. The freckled youth should have been treated to a much softer and bolder grain—your effect is hard and white, and lacks finishing. In other respects your work is very good—far above average—and if you take our remarks to heart there is no reason why you should not shortly seek a situation in a first-class firm. We never suggest or attempt to fix stated salaries—that you must ascertain through answering our advertisements and making the best terms you can.

**W. H. D.**—(1) The lens is as good as you can get for such portable work. (2) The Tress Company, 42, Oxford Street, W.

**DEVELOPMENT.**—(1) What formula do you recommend for standard development for extremely rapid exposures? (2) Is pyro-sol advisable under such circumstances?—SNAPSHOT.

(1) 1 in 200 rodinal. (2) Not so suitable as rodinal.

**W. FIELD.**—It is not a copyright question, but one of libel. As we do not know the circumstances of the accident we cannot say if the company's plea that they were not to blame is sustainable. If you think it is, you had better withdraw the enlargement, which certainly implies negligence on the part of the driver. The matter hinges on this. So far as copyright is concerned, you can dispose of that, and wash your hands of further responsibility.

**MATERIAL FOR SHOP WINDOW.**—Can you tell us of any material (preferably green) suitable for floor of window that will not flake in the sun? We have tried velveteen, baize, and several other stuffs, but all turn to a dirty brown in the sun during the course of a few months. We require something that will have a good class appearance.—SHOW-CASE.

We know of no material suitable for the purpose, the colour of which will not change, more or less, by prolonged exposure to strong sunlight. If you go to a high-class upholsterer's and mention what you require they may possibly be able to supply you with something with a stable colour. However, if you have good woollen fabric, and its colour fades, you can have it dyed Greens, as a rule, are not very permanent colours.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Mr. C. H. Hewitt, in an article on the use of enclosed arcs in studio portraiture, gives a good deal of useful information to those using up this form of artificial lighting. (P. 840.)

Some further notes on the same subject emanating from Mr. Howard Farmer deal with electrical matters and the photographic efficiency of the enclosed arc. (P. 842.)

Further abstracts of Baron von Hübl's papers on "Artificial Lights" appear on page 844.

We regret to record the death of Mr. John A. Hodges at the age of forty-six. (P. 845.)

Part of the musical programme at the R.P.S. dinner last week has been read the letter from a correspondent on page 854. Amongst the correspondence are letters dealing with an anti-frill dish for Autochromes and with Rodinal developer. (P. 854.)

Precautions in reversing and intensifying Autochrome plates appear on page 839.

Mr. C. L. A. Brasseur, in "Camera Work," appears to suggest that the ratios of three-colour filters require alteration under different weather conditions. (P. 843.)

Colour-photography figures in two notable society reports this week, namely, Mr. T. K. Grant on the "Autochrome Plate," at the Royal (page 851), and Mr. Henry J. Comley on "Three-colour Carbons" at the Southampton Camera Club. (P. 852.)

A reversal process, similar to that used with Autochrome plates, is recommended by Mr. C. R. M. Parr for making enlarged negatives direct. (P. 846.)

A method of focussing depending on the coincidence of two divided parts of an image has been patented. Other patents of the kind include a developing tank and enamel process. (P. 846.)

Some notes on the practice of matt carbon printing appear on page 838, and will be concluded next week.

## EX CATHEDRA.

### Baryta Coating.

In a recent paper before the "Union Nationale des Sociétés Françaises," M. R. Guillemot has been recording his experience in the preparation of the raw paper employed for bromide and P.O.P. emulsions. Epitomised, M. Guillemot's experience amounts to the use of absolutely pure and white gelatine of medium hardness, and of a sulphate of baryta prepared from the carbonate (not the by-product from the manufacture of hydrogen peroxide). He finds that the proportion of gelatine to baryta in the coating should be from 10 to 8 parts of gelatine to 100 of baryta, the former for matt papers and the latter for glossy. He finds that other constituents than these two are of no advantage for the preparation of a paper intended to carry a bromide emulsion.

\* \* \*

### A. L. Coburn and the Autochrome Plates.

If we are to believe the views alleged to have been expressed to an interviewer by Mr. Alvin Langdon Coburn, the Autochrome process in pictorial photography is to fulfil the eminently useful purpose of dividing the sheep from the goats, or perhaps we should say of providing a definition of sheep and goats respectively. A correspondent of the "Liverpool Courier" prints in the issue of that paper of October 31, what purports to be a conversation with Mr. Coburn, in the course of which the latter explained why he and others, who, it appears, represent the "photographic" school in pictorial photography (other schools being "jugglers" and "crazy-quilters") are able to see possibilities in the process. The "unfakeable" Autochrome plate, laments Mr. Coburn, is not for those who remedy an ill-exposed plate by manipulating an oil print, or who, in building up a picture, juxtapose a farmyard from Kent, a Scottish sky, and a mountain from Wales. In short, the Autochrome is for the "straight" photographer, and no "faker" is to have part or lot therein. Mr. Coburn has photographed George Bernard Shaw, and has produced a number of results quite beautiful in their colour schemes. When we inspected these the other day we had it from Mr. Coburn that he deviates from the Lumière procedure.

\* \* \*

### Colour Harmonies and Colour Contrasts.

So much has been dinned into the photographer as regards these matters in their application to the mounting of photographs, that it should only be necessary to emphasise the similar dangers which he runs in his essays in colour subjects. As a rule the beginner is well advised to seek his effects in harmonies of colour. He is safer in taking that course than in attempting the more difficult task of obtaining a contrast of colours which is not discordant. There is equally harmony in contrast. Paradoxical as the phrase sounds, a walk in a London suburb on a Sunday afternoon will supply a score of instances of

discordant contrasts in the promenading feminine attire. The photographer who aims to succeed in genre or portraiture in Autochrome work—a most promising use of the new plates—can find no better opportunity of studying the massing, harmonising, and contrasting of colours than in the ballets which a house of entertainment such as the Alhambra puts on its boards. An hour spent in witnessing the constant change of characters and costumes will give the practical portraitist plenty of ideas as to the colours he can and cannot place together before the camera when making a study in colour.

\* \* \*

#### Bleached Shellac.

The Journal of the Franklin Institute contains a paper on the analysis of shellac, by H. Endemann, that is somewhat technical, but contains at least one item of information of practical moment to photographers. It is stated that bleached shellac, prepared by bleaching with hypochlorite of soda, contains chlorine, one sample retaining as much as 1.26 per cent. chlorine. Bleached lac is frequently used as a negative varnish, and sometimes as a mountant, and whilst it is not certain that the chlorine is free to do any damage to the negative or print, it is certainly not a desirable companion for a photographic silver image. While we have never heard of any trouble due to the use of bleached lac, it is, of course, quite possible that it may have led to some detrimental effect that has been attributed to something else. We must, therefore, regard it as somewhat under suspicion until rather more definite information is obtainable.

\* \* \*

#### For Whom Photography Sufficeth Not.

The camera is usually charged with the responsibility for the existence of the arm-chair type of person, traveller, novelist, or historian, and therefore it is interesting to hear of instances in which its records of scenes and customs have been considered not good enough for even such ephemeral work as modern fiction. Miss Beatrice Grimshawe, it appears, has made a small sensation in the South Sea Islands by appearing there in company with a tea-kettle, a looking-glass, and a typewriter, in order to get the right local colour into her series of Pacific stories. The islanders were more puzzled by the apparition than by a photographer's under the focussing cloth. Their first impressions put it down to an evil spirit, which, as the "Pall Mall Gazette" remarks, might be regarded as not very wide of the mark, since it ultimately proved to be a lady novelist.

#### MATT CARBON

In spite of undoubted permanence, beauty, and adaptability carbon has not yet come into its own. Doubtless the process will become even more popular when the slightly glossy or "carbon" surface is more generally rejected in favour of the matt surface, which is equally easy to produce.

During the vogue of albumen paper, when portrait brown and portrait purple tissues had to be used to make the process at all saleable, the surface from flexible support, resembling as it did that of the then universal process, was an advantage rather than a drawback. Nowadays, however, with the improved taste of photographer and public alike, the perfect matt produced by direct transfer from opal plates is much more desirable.

We think that for the beginner the flexible support is easier to work, but any one thoroughly well up in manipulation will soon be equally or more successful on rigid supports. Apparently the only disadvantage against opal is the idea that the shadows look leathery. We have not the same depth and transparency as those on a flexible support. In the case of an ordinary good professional negative, with no clear glass portions, we do not think that this idea is correct, although naturally carbon, as with other processes, a glossy surface is more flattering to a poor under-exposed negative than is a dead matt. The rigid support has not the same range of usefulness as the flexible, since the latter must be used for final transfer on to rigid bases, such as wood, ivory, or opal, or on to a flexible base of a coarse texture, such as canvas and rough drawing paper. This, however, matters little, since these materials are unusual in ordinary work.

In working with opal supports to the greatest advantage it is necessary to have a little special apparatus, consisting of zinc racks, with grooves, to hold the plates particularly, and tanks in which rack and plates can be entirely submerged by the solutions. With these the photographer will find opal supports are quicker, easier, and more certain than paper ones. Waxing itself is more satisfactorily done, flexible supports being liable to buckle thus cracking the prepared surface. Opal must be more fully treated, however. It is necessary to wax and print only one plate at a time, and that well away from others, since the plates sometimes slip suddenly, and will chip or break entirely any plate they strike. The only trouble one has when waxing opals is that the print has a tendency to refuse to leave the new plate. It is advisable to pre-

### THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

Among other alterations and improvements which have been made in the forthcoming volume, the publishers beg to announce that:—

All three indexes (text, advertisement, and trade addresses) will be found AT THE END OF THE VOLUME.

The size of the volume has been appreciably reduced, without sacrificing the value and scope of the contents.

The editorial article will deal very completely with the important subject of—

SCREEN-PLATE THREE-COLOUR PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The 1908 ALMANAC will contain as frontispiece a card printed by the Autotype Co., dry-mounted by the Adhesive Dry Mounting Co., Ltd. Amongst other attractive items will be found a specimen of three-colour printing by Sanger-Shepherd Colour Printing Co. and examples of three-colour work of Hood and Co., Ltd., Middlesbrough.

Our publishers desire us again to caution our readers against postponing the booking of their copies of the ALMANAC.

#### PUBLISHERS' NOTICE.

The publishers beg to inform agents that it will be as well to place their orders for copies immediately, as this issue is always booked before publication, and a second edition will not be printed.

plates by waxing and polishing two or three times using ordinary turpentine, white solution, perfectly satisfactory for flexible support, is not so for opal. A solution of

Beeswax .....	30 grs.
Yellow resin .....	100 grs.
Benzole .....	20 ozs.

to be used. Since the benzole evaporates very quickly the plate may be rubbed with this mixture and immediately polished. The rapid evaporation makes it unnecessary to prepare the plates long before they are required, minutes being a sufficient interval. It will be found necessary to prepare the plates every time a transfer is made; after six waxings the plate will be sufficiently imitated to allow of quite four or five transfers before waxing, and even this may be dispensed with as the wax gets old. When required the plates should be placed in rack all in one way, plunged into tank of cold water, and moved

up and down once or twice to remove any airbells on the surface. It is advisable to put the rack so that the matt surfaces of the plates will always face one way in the tank, preferably towards the worker. This is recommended, as it is difficult to tell the right side of the opal when wet, but if the above precautions are taken the matt side will always be placed uppermost on squeegeeing board from force of habit. The tissue may be put into the water immediately the plates are covered, there being no necessity to wait as with flexible support. When the first piece of tissue is soaked sufficiently the opal is laid on the board and flooded with water; the tissue is then taken by opposite corners and laid diagonally in contact, the corners held in the hand are dropped, and the squeegee used somewhat heavily, taking care, however, not to tear tissue. Under no circumstances should the plate and tissue be brought into contact under water; dust will certainly get imprisoned between the surfaces, no matter how clean the water appears.

[Some notes on the further procedure must be reserved for next week.]

## AUTOCHROME ITEMS.

### Green Stains on Autochromes

so familiar green stain produced when the edges of an autochrome begin to frill is commonly attributed to the readiness of the green dye. We have, however, heard it suggested that it is more likely to be due to the running and washing of the blue and red dyes, which suggestion assumes that fringed parts are green owing to the presence of the green grains. Testing this matter, it appears that the first suggestion is more nearly correct. If an abraded screen is put under the microscope and a drop of water is placed on the screen the rapid solution of the green dye can be readily observed. This seems to be the most soluble of the three dyes, the red also speedily washes out, while the blue does not appear to be affected by water, though it is soluble in alcohol. If an emulsion is stripped from an Autochrome, a dip in alcohol will enable the waterproof film covering the starch to be rubbed and rolled off with the finger. This film is dissolved by the alcohol, though apparently it is not soluble. If a starch film is then immersed in water a green solution is rapidly produced, and the microscope will show that the starch is soon quite washed out, while the red is very nearly so. However, the starch film is immersed in alcohol a blue solution results. A little green is also washed out, but this may be due to the water present in the alcohol. A mixture of alcohol and water attacks all three dyes, but the blue does not dissolve at all readily, while the red takes some time to disappear. It appears, then, that the green stain must be due to the running together of the green and red dyes. When the green predominates, and so in place of the three colours we have green and blue only.

### Reversing Autochromes.

Many proposed alterations in the procedure of making autochromes there is, at any rate, one that we find to be useful. Gravier does not keep the reversing solution of permanganate and sulphuric acid ready mixed, but adds the other solution just before use. Quite independently of Gravier's suggestion, we have also arrived at the conclusion that the freshly mixed solution is far more satisfactory. A mixture of permanganate and acid after long keeping will not give the silver image, but it does not by any means act in the usual fashion of the fresh solution. With a very stale solution the whole image is covered with a brown scum, and generally

sprinkled over with specks that are not readily removed, but with a freshly mixed solution a clean result is obtained. We have, therefore, adopted the practice of keeping separate solutions of permanganate and sulphuric acid, and we do not mix them until just before use. It has been stated by some that the stain produced by the reversing solution is of no consequence as it disappears in the redeveloper. We are, however, doubtful if the heavy deposit produced by a very stale solution does completely disappear. In any case the specks of manganese compound do not do so at all readily, and the attempt to remove them by wiping often results in damaging the film. The scum referred to can be wiped off readily with cotton-wool, but the specks remain. With fresh solution there is no necessity to wipe the film at all; there is therefore less risk of damage, and time is saved.

### Intensification of Autochromes.

Intensification of Autochromes with the silver intensifier sometimes produces bright metallic specks over the image that cannot be completely removed. There are two causes of this, and both can be avoided by taking a little care. The stock solution of silver invariably precipitates metallic silver if kept for a little time. This deposit falls to the bottom of the bottle and, if not disturbed, does no harm, but if a nearly empty bottle is drained into the measure when preparing the intensifier, or if the deposit is stirred up by refilling the bottle just before use, the silver particles get into the intensifier and on the plate. The precautions that should be taken are obvious. The bottle should be cleaned out before refilling, and it should neither be shaken up before use nor drained right out to the last drop. The other source of silver specks is the use of dirty measures, etc. The measure employed should always be cleaned before re-use, and the neck of the silver bottle should be wiped free from dust and silver deposit. In fact, the matter of cleanliness cannot be overdone when dealing with silver intensification. If it is desired to intensify after fixing, the plate should be washed for a few minutes to free it from hypo, and then be immersed in water just tinted pink with plain permanganate for about twenty seconds. If the solution loses its pink colour more washing is required, but if the pink is retained intensification can be proceeded with after about half a minute's washing. After intensification the usual clearing and fixing baths are used, and the plate is given its final washing.

### Residues from Autochromes.

Autochrome workers are very apt to forget that one of the solutions used contains silver residue well worth preserving on account both of its quantity and of the automatic way in which it can be saved. The silver intensifier deposits a very small proportion of its silver on the image, and there is no need to waste the remainder. If thrown into a large bottle and left for a few hours the silver is deposited without the assistance of any additional reducing agent, and it is also deposited in a fairly clean condition. If half the fluid contents of the bottle is carefully decanted each day in the course of a few weeks a very respectable quantity of silver will be collected. This is a matter that should

not be overlooked by professionals inclined to take up the commercial production of Autochrome portraits. As regards other solutions, the hypo solution is used more or less as a simple clearing bath. It is not a fixing bath in the ordinary sense, can contain only an infinitesimal proportion of silver; therefore it is not worth consideration. The reversing bath contains silver, but only in very minute quantities. The silver removed from an Autochrome can only be a small fraction of quantity that the fixing bath takes from an ordinary negative while the residue obtained is mixed with a large proportion of manganese compound. It is therefore hardly worth preservation, though the used intensifying solution certainly should be saved.

## THE ENCLOSED ARC FOR STUDIO PORTRAITURE.

SOME idea of the importance of electric lighting of studios for portraiture may be gathered from the great variety of systems which have been adapted to the requirements of the portraitist. The only illuminant which is not quite commonly used is acetylene, excluding, of course, the comparatively feeble oil-lamp. Incandescent electric, open and enclosed arcs, pressed incandescent gas, and both high and low voltage mercury vapour lamps are all available, in many cases in such a form that the photographer has nothing to do but buy the lamp and at once commence exposing plates with it. This "complete outfit" idea is at once a strong and a weak point. To the worker who does not thoroughly grasp the essential principles of artificial light work, or, in other words, who does not know exactly what he ought to have and how to get it, the "ready for work" lamp saves trouble, relieves him of a certain amount of responsibility and worry, and usually ensures that the cost of the installation shall not exceed a known sum. On the other hand, the area, height, and shape of studios vary so much that what may be satisfactory in one building will not work so well in another, and the photographer who, with a clear grasp of his requirements, can fit up an installation specially adapted to his own studio and his own individualistic style of work will often gain a good deal in efficiency, and perhaps save something in cost.

The enclosed arc, as it exists commercially, for example in the "Westminster" lamp, possesses this advantage, then, that with its resistance and the necessary length of cable, it is a complete source of light which may be placed anywhere in the studio, giving a highly concentrated light, which the photographer must distribute properly for the effects he desires to obtain. The more control can be obtained over the distribution the better, and it is in many ways an advantage to start with what is practically a point of light. To say this of the enclosed arc lamps is not to disparage other forms of illumination. Each has advantages and attendant drawbacks, and here, as in all other matters, there can be no best in a general way, although in any particular set of circumstances the *summum bonum* may rest with one type.

### Systems of Arc Illumination.

With regard to the distribution of the light there are two methods—reflection and diffusion. The direct light may be received by some white surface of considerable area and thrown back in the direction of the sitter, or it may be allowed to pass through some translucent medium, as engineer's tracing linen or mineral paper or ground glass, being refracted in so passing, and thus so scattered as to produce a softer illumination. Reflection should always be employed, or else a considerable waste of light occurs. In some cases all direct light is cut off from the sitter by a small opaque plate of metal, only the reflected light from the large white surface being available for lighting the portrait. Both methods may be employed in con-

junction—that is, between the arc and the sitter some diffusing medium is placed, and on the opposite side of the lamp from the sitter is fixed a reflecting screen. In this way the maximum of illumination is obtained. A method which has been found quite satisfactory in practice will be given below.

It must be remembered that, though in a well-constructed studio for daylight work it is not only possible but very desirable to work without any auxiliary reflector for softening the shadow side of the head (that is, none other than a quite neutral paper on the studio walls), in artificial light portraiture such a shadow side-reflecting screen becomes practically essential. Size, colour, and nearness to the sitter of this shadow side-reflecting screen must to some extent be determined by the strength of the direct light, the character of the diffusing medium employed, and the area of the principal reflector of the lamp itself. To prevent any confusion, the term "lamp reflector" will uniformly be applied to the white surface behind the lamp, which throws back the light in the direction of the sitter, and is thus, so far as the portrait is concerned, either the whole or a part of the principal source of light. The other reflector for lightening the cast shadows will be uniformly referred to as the "shadow side-reflecting screen."

### An Artificial Light Studio.

The simplest possible arrangement, and one admirably suited to a studio of the "lean-to" type, is that shown in the diagram on next page.

Here the enclosed arc lamp is suspended near the wall of the studio by a flexible wire cord over two pulleys, and is balanced by a counterpoise weight. A thin steel wire cord should be used so that the difference in weight between the two sides is immaterial when the lamp is raised or lowered. If the pulleys are slightly stiff this difference is compensated by friction. The wall behind the lamp should be covered with cartridge-paper of as white a character as possible, and as this gets soiled with age it may be coated with dead white distemper. The area of the papered wall, i.e.—the lamp reflector—may go as high as possible, come down to within 5 ft. of the floor, and extend laterally from a point level with the sitter's chair for about 8 ft. in the direction of the camera. The lamp may be hung centrally at this 8 ft. A large greenish blind should be made to draw down over this white-papered wall so that the strong reflection from it may not interfere with daylight work. Alternatively the lamp reflector itself may be a white blind, but it will require painting from time to time, and may be liable to crack as the paint accumulates in thickness. Between the arc and the sitter an ordinary translucent head screen may be placed, as shown in Fig. 1, and there is a better material for covering this than thin engineer's tracing linen. Paper is apt to be broken with the least touch, and fabric, such as cheese cloth or butter muslin, is in danger of

catching fire, whereas tracing cloth is saturated with, possibly, gelatine, and is comparatively non-inflammable.

### A Comparison of Daylight and Artificial Light.

Let us see, now, how this arrangement compares with the daylight method with which photographers are already familiar. A very common daylight arrangement is to have thin muslin blinds or curtains, or frames of wood fitted to the window and covered with mineral paper, and over these opaque blinds of dark blue or green blind holland. The whole of the light may be cut off where not wanted, and one of the muslin blinds or paper-covered frames may be removed when a more direct and

concentrated beam of light is required to produce the "tipped high lights." With the suggested enclosed installation, the large area of white wall forming the lamp reflector provides the softened general illumination, while the more concentrated beam is provided by the direct rays from the lamp filtered or diffused by the tracing-linen head-screen. By raising or lowering the lamp by means of the counterpoise weight this more concentrated beam may be directed on to the head from a higher point or from a lower, as it is felt more top or more side light is necessary for the adequate lighting of the head under consideration.

If the light is wanted more from behind or more from in front of the sitter three courses are open to the operator. First, the lamp may be so arranged that it will slide on a rod nearer to the background or further away from the background. This is at best a somewhat clumsy device, and not to be recommended. Second, the sitter may be moved forward or backward, which is simpler and less worrying to both sitter and operator than the moving of a swinging lamp. Third, and simplest of all, where the studio is of adequate width, say 12ft. or 14ft., the camera may be moved nearer to one side or the other of the building. Thus, if the light is wanted rather more in front of the sitter this effect will be produced by moving the camera nearer to the wall against which the lamp is hung, the sitter, if a full-face portrait is being taken, turning the head towards the camera. If the light is wanted rather more from behind the head, the camera is moved a little towards the opposite side of the studio. In actual practice almost any modification re-

quired can be obtained in this way without the need of shifting the lamp at all, except to raise or lower it.

As in almost all cases the lamp is to the front of the camera, some efficient form of lens shade is an absolute necessity. If this is so arranged that no light reaches the lens at all, except that which forms the image on the plate, so much the better, and the makers of the better forms of studio camera might surely design such a lens shade, worked by an extension-rack and pinion, so that the rectangular opening in front of the lens could be moved forward or backward to correspond with the movement of the focussing-screen nearer to or further from the lens.

### Reflecting-Screens.

Turning now to the shadow-side reflecting-screen, we may consider what the requirements are in this direction. As suggested above, we find in daylight studios a much greater volume of diffused light throughout the room, and if the walls are of a neutral shade there is much reflected light from all directions, which softens the shadows of the portrait. With electric lighting this general diffused light is absent, and it consequently becomes necessary to adopt other means for softening the shadows. What is wanted is really a sort of artificial wall which may be placed in any position relatively to the sitter and the lamp so that the reflected light for softening the shadow side of the head may be as much under control as the direct light. The best form of shadow-side reflecting-screen is an eight-foot background-frame on its castors, covered with a square of grey calico. This screen may then be kept a fair distance from the sitter, and false reflexes in the eyes to a great extent avoided, whereas a small screen would have to be placed much closer, and would give false reflexes or blind spots in the eye—really a small reflected image of the screen on the surface of the eyeball.

The best position for this shadow-side reflecting-screen is not on the opposite side of the head to the source of direct light, but so that the light and shadow sides of the face are properly blended. This implies an oblique position slightly to the front of the sitter, the screen, in fact, being so placed that the lens will just look past its edge. Of course, ordinary everyday full-face or three-quarter face lightings are referred to, and if these can be properly lighted the experienced daylight worker will have no difficulty in making such modifications as will give him anything he requires in the way of fancy lightings.

### An Exposure Question.

Two points connected with exposure may well be mentioned in any consideration of electric lighting. Slight variations in the distance between the sitter and the lamp will produce considerable differences in exposure. Thus, if one second is the requisite exposure when the head is 6ft. from the lamp, an increase of distance to 8ft. 6in. will necessitate an exposure of two seconds, the exposure varying as the square of the distance. Thus, 8½ft. squared gives 74, which is rather more than double 36, the square of 6. Two feet six inches is not a great distance to move a sitter when arranging a fresh pose, and the point needs constant watching if exposures are being reduced to the minimum.

Further, the greater the distance from the sitter the longer the exposure, assuming the same size of image—that is a 2in. head with a 16in. lens will require a longer exposure than a 2in. head with a 16in. lens will require a longer exposure than a 2in. sitter to lens. In daylight work it is customary to give possibly half the exposure for a full-length or three-quarter length that would be necessary for a head and shoulder portrait, but with electric light practically the same exposure will be necessary in both cases.

It should be remembered, however, that with a good enclosed arc lamp exposures may be very short indeed, a quarter of a

second at F. 5.6 with a 200 H. and D. plate being an ordinary timing. These figures will hold good with the "Westminster" lamp. There is thus no need, as a general thing, to cut down exposures unduly, and the latitude of the best modern dry-plates

is such that if reasonably full exposures are given, there is little danger of going wrong even if the distance from sitter to lamp or sitter to camera does slightly vary from one exposure to another.

C. H. HEWITT, F.R.P.S.

## ENCLOSED ARC LAMPS IN THE STUDIO AND PROCESS SHOP.

[The following notes by Mr. Howard Farmer, issued as a circular by the Westminster Engineering Company, Victoria Road, Willesden Junction, N.W., supply advice on technical electrical matters which is often sorely needed by photographers commencing or contemplating the use of an enclosed-arc installation.—Eds., "B.J."]

WHEN equipping a studio for copying or process work, in which electricity is the source of illumination, by far the most important item in the success of the studio will be the details of the electric light installation. The first aim of a business man will be to avoid unnecessary expense in the equipment, and with this end in view there will be a tendency to order each pair of lamps with their individual and attendant fittings, such as switches, resistances, etc., of the least expensive type. But a consideration of the conditions which prevail in photographic work will show that this is not a good policy.

In the studio the current may be switched on and off every few minutes, and necessarily in a hurried and even violent manner; therefore switches which are good enough for ordinary lighting purposes may be broken or loosened in all their parts in a week or two if used for photographic work.

### Switches and Adjustable Resistances.

It follows from this example that the switches selected should be such as are capable of withstanding hard wear and rough usage. In ordinary lighting lamps a non-adjustable resistance is included, which absorbs a portion of the electric energy, and if the photographic work is confined to small copies (not more than 12 or 16 inches) and to black and white subjects only, it may be satisfactory on the score of simplicity and uniformity to adopt the same method, but if large drawings have to be copied or colour work is included in the requirements a very great advantage will be found from using a resistance fitted with a regulating switch. By means of this apparatus the best possible results can be obtained from the lamp, and far greater economy and efficiency will be obtained. The regulating switch enables the operator to cut out some of the resistance after the lamps have started, and thus secure for his exposures the advantage of the extra power obtained by the longer arc. In actual practice the increased efficiency and economy gained by this arrangement is equal to a second pair of lamps—that is to say, the operator secures an illumination of his copies when required equal to four lamps instead of two. From this it follows that not only should strong switches be specified, but also that they should be fitted with a graduating resistance of five or six steps. The wiring should in all cases be amply large to allow for increase of current when necessary without risk or unduly heating the wires. A further advantage of the adjustable resistance is that it gives a very convenient and instantaneous means of equalising the illumination on the two sides of the copy.

### Lamps and their Photographic Efficiency.

It is, however, when we come to the lamps themselves that we find the greatest differences in economy. It is not overstating the case to say that the difference between two makes of lamps, equal to one another as regards their illuminating power and using the same current, may be such that the exposure with one may be as much as eight times longer than the other—that is to say, each exposure with the inferior lamp costs the proprietor eight times as much for current as the better one, and this without including the loss due to the delay of the whole establishment or the alternative of providing additional complete equipments with their necessary complement of space and operators.

The explanation of the difference in the efficiency of the lamps lies chiefly in the fact that the rays efficacious in ordinary photography are the violet and ultra violet, neither of which have any value as illuminants. The violet rays, indeed, are worse than useless as illuminants, and they give an objectionable cold and violet hue to

objects generally, and to the human features and complexions specially; therefore, as far as illuminating purposes are concerned, the aim of the lamp designer is to suppress these violet rays as much as possible, and it follows also that the design of lamps for photographic purposes requires special study on the part of the electrician.

During the past few years one of the firms of high repute who have paid special attention to these requirements is the Westminster Engineering Company, Ltd., of Victoria Road, Willesden Junction, to whom the photographic publishing and engraving trades are under a deep obligation for the improvements in lamps, and the greatly increased efficiency in working thereby attained which have resulted from their efforts.

With the open type short arc the intensity of the radiation in different directions is very uneven, and in any one direction variable, the two effects together giving rise to serious elements of difficulty and uncertainty in working. With the long arc these defects are, comparatively speaking, absent. From these various considerations it is obvious that the enclosed arc for all photographic purposes is a greatly superior type to the open arc lamp.

For copying or making screen negatives from small originals—black and white, their small lamps, No. 110c or No. 111c, with reflector fitted, and with fixed or variable resistance, will be found reliable and sufficiently powerful for quick exposures.

For copying large originals and direct screen colour work the large lamp, No. 114 type, should be employed, with a variable resistance, the best conditions being with a direct current voltage of 200 to 250 if possible.

By taking advantage of the co-relation which exists between the different rays, carbons are now constructed which transform a maximum of the available energy into red and yellow rays, green rays, violet rays respectively, and in colour work these special carbons are employed for the blue printer, red printer, and yellow printer respectively. For the purpose of changing the carbons readily, it is important that the lamps should be strong and flexible in the mounting parts and the enclosing system simple and accessible. Here again the "Westminster" lamp, with its plain cylindrical glass loosely resting on the lower flange, together with the tubular spring clip for the upper carbon, and single screw for the lower, gives the maximum of simplicity and reliability.

As each colour record is taken separately with a light which gives a proper spectrum record for that colour, so long as the proportion of exposures are correct, it is of no importance that the original looks altogether wrong to the eye with either of the carbons when illuminated singly by them.

Average exposures for screen negatives with lamps working on direct current with 240 volts, 11 amperes, 16 inches from the copy.

	Stop.	Exposure.	Carbons.
Black and White Wash Drawing			
with Wet Collodion .....	F/90 .....	3 min. ....	Plain
Ditto. Ditto. ....	F/45 .....	30 sec. ....	hard solid

### Water-Colour Drawing with Albert's Emulsion.

	Stop.	Exposure.	Carbons.
Blue Printer.....	F/128 .....	10 sec. flash .....	Flame red
Ditto.....	F/128 .....	3 min. on copy .....	Ditto
Red Printer.....	F/128 .....	15 sec. flash .....	Ditto
Ditto.....	F/128 .....	4 min. on copy .....	Ditto
Yellow Printer.....	F/90 .....	4 min. ....	Plain
Ditto (wet collodion).....	F/45 .....	30 sec. ....	Hard solid

### Portraiture.

For portraiture the most suitable lamp is the No. 114, carried on

a suitable stand or suspended from an overhead carriage, depending upon the arrangement of the studio. One lamp is quite sufficient, with a reflector behind, and a suitable diffusing screen between the subject and the light, movable reflecting surfaces being arranged on the opposite side. The reflecting surfaces may be made of white blotting-paper or other highly reflecting matt materials.

The diffusing screen may be made of ordinary white tracing linen

stretched over a light hoop and carried on a movable and adjustable stand.

Exposures will be found to vary with the distance of the lamp from the subject and the current used. With the lamp 6 feet distant and taking a current of 15 amperes on 200 to 240 volt circuit, the exposure with  $f/6$  will be from  $\frac{1}{2}$  of a second, of course depending on the plate used.

HOWARD FARMER.

## WEATHER CONDITIONS AND COLOUR PHOTOGRAPHY.

A paper in Mr. Stieglitz's quarterly "Camera Work."

AMONG the many problems connected with that of taking photographs in natural colours is one the solution of which, though of extreme importance, has received but scant attention from investigators. I refer to that peculiarity that, while certain photographs must represent the objects in the colours in which they are seen at the time of taking, a great many others must be made to represent the objects as they would appear if illuminated by white light. Reproductions of landscapes and exteriors belong to the first category, while reproductions of paintings, art objects, etc., belong to the second. Portraits, also, generally belong to the second, but, for reasons to be later developed, they, as well as mural paintings and frescoes, may, in some cases, be classed in the first category.

A moment's reflection will show the reason for this classification. It is evident, even to the most unobservant person, that the colour of a landscape varies enormously at different hours and on different days. These differences in colour are not only those due to the progressive absorption of the different light rays by the increasing thickness of the atmospheric stratum as the sun sinks lower and lower, but are also due to local atmospheric conditions. It is clear that a colour photograph of such a landscape must be a faithful interpretation of the conditions existing at the time of the taking of the photograph.

THE "RAJAR" CAMERA offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P. has been awarded to L. H. Taggart, Douglas, having been judged the best received during October. The paper on which the print was made was purchased from Mr. Aspell, Bucks Road, Douglas.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—The second annual exhibition of this society will be held at the Islington Public Library, Manor Gardens, Holloway, N., on December 5, 6, and 7. There

be able to modify the quality of the light reaching the plate so as to make it the equivalent of white light.

If this be judged too glaring, it can, as will be shown later, be mellowed to any extent.

Exception has purposely been made to the colour-reproductions of frescoes, mural paintings, etc. These, in justice to the painter, must, if possible, be reproduced in their setting and in the light in which they are intended to be seen.

### Atmospheric Absorption of Light.

The following figures, deduced from the formula given by Lord Rayleigh in the "Phil. Trans." of Royal Society, 1887, show how important are the variations in the quality of the light at different hours of the day.

Assuming that sunlight before traversing the atmosphere is made up of 1,000 parts of each colour, the amount of the different colours transmitted through varying thicknesses of atmosphere will be as shown in the table, the figures 1, 2, 3, 8 being the relative thicknesses of atmosphere traversed, and 90deg. to 30deg., etc., indicating the elevation of the sun above the horizon.

	1. Atmosphere or 90°.	2. Atmosphere or 80°.	3. Atmosphere or 19°30'.	8. Atmosphere or 7°30'.
Red at B .....	945	855	795	550
Orange at C .....	910	835	760	480
Yellow-orange at D .....	865	785	655	325
Green at E .....	805	645	520	170
Blue at F .....	735	545	405	85
Violet at H .....	510	250	120	0

As will be noticed, sunlight in traversing 1 atmosphere loses about 9 per cent. of the red and nearly 49 per cent. of the violet; when it traverses 2 atmospheres, it loses 15 per cent. of the red and 75 per cent. of the violet; and when it traverses 8 atmospheres, a little before sunset, it has lost 45 per cent. of the red and 100 per cent. of the violet. At 32 atmospheres, the sun being at the horizon, the yellow, the green, and the blue and the violet are entirely absorbed.

The above table is for normal absorption. It is clear that there is an additional variation due to local atmospheric conditions, such as clouds, rain, haze, etc.

Such being the working conditions of the colour-photographer, it follows that instruments must be used to measure, quickly and accurately, the quality of the light at the time of the taking of the photograph, and must, moreover, have means in his lens to quickly make such corrections as may be necessary to ensure faithful reproduction of an object as it would appear in white light.

C. L. A. BRASSEUR.

will be two open classes—one for "pictorial photography," in which three bronze plaques will be placed at the disposal of the judge, Mr. Furley Lewis, F.R.P.S., and the other for "colour photography," any subject in either prints or transparencies, though preference will be given to the former, the award being one bronze plaque. Entries close November 25, and entry forms, which are now ready, may be obtained from the hon. secretary, Mr. C. H. Madden, 12, Dagmar Road, Stroud Green, London, N.

## ARTIFICIAL LIGHTS IN PHOTOGRAPHY.

## II.

[An abstract of recent papers, by Baron von Hübl, in "Das Atelier."]

## Various Kinds of Arc Lamps.

The arc light is caused, as is well known, by the passage of an electric current between two carbon points which do not touch (Fig. 5). In consequence of the high resistance of the air, very great heat is produced. According to Thompson,<sup>1</sup> the temperature is about 6,840deg. F. At this temperature the carbon points glow, become vaporised and burn, particles are torn off, and fly to the opposite pole, and there is thus formed a glowing bridge of light. The temperature of the two poles is not the same. That of the positive (+ in Fig. 5) is the hotter, and is therefore more quickly destroyed than the negative.

After a short time there forms in the positive pole a depression or crater, *a*, which corresponds to the hottest part, whilst the negative pole burns away to a point. The positive crater emits a very intense light, in comparison to which the negative pole is comparatively dark.

The arc of light is of different lengths and brilliancy, according to circumstances. In the ordinary arc it is short and not very luminous, whilst with some of the newer types of lamps it is much longer and of great brilliancy, so much so that the crater light is scarcely perceived.

The length and brilliancy of the arc can be increased by increasing the current or by addition of certain substances to the carbons, which, at the temperature of the carbons, are vaporised, and form a good conducting bridge. Such carbons are known as "effect" carbons, the arc formed between them as "flame arcs."

Fig. 5.

There are two types of arc lamps, one with a short arc, in which the positive crater emits the light. This is the ordinary arc lamp; those with long, brilliant arcs are called "flame" or "high-tension" lamps.

If ordinary carbons are used the arc always emits a light very rich in blue, violet, and ultra-violet rays, and as it is these rays which are photo-chemically active, it is clear that lamps with long arcs are the most efficient in photography.

## The Ordinary Arc Lamp.

In the ordinary arc lamp, working at about 45 volts, the arc itself is scarcely visible, and is of little value for printing. The light is emitted from the crater, *a* (Fig. 5). A curved surface of this nature acts like a luminous surface.

The radiation of the light from the crater is partially stopped by the negative carbon; even at *mm* (Fig. 6) the decrease of the light caused by the shadow of the negative pole is seen, whilst at *nn* there is complete darkness. The radiation of the light is thus considerably contracted, and the intensity curve corresponds not to the circle, *K*, but shows the shape of the curve, *C*. The strongest light is thus radiated downwards at an angle of 40deg. to 50deg., whilst in an horizontal direction the intensity is nil, if the small radiation from the negative pole is neglected.

The extension of the light rays corresponds to a body moving round the axis of the carbons. If, as shown in Fig. 7, a plane, *FF*, is illuminated parallel to the lamp axis, the "illumination

curve" is *KK*. To obtain this, the variation of light from intensity curve, *C*, the "radiation angle" has to be multiplied  $\cos^2 \alpha$ , as mentioned in the previous article. If the plane is tilted so that it is at right angles to the rays at 40deg. in the position shown by the dotted line, *F<sub>1</sub> F<sub>1</sub>*, the "illumination curve" becomes *K<sub>1</sub> K<sub>1</sub>*.

It will be seen that these curves are always very sharp, in consequence of the obstruction to the radiation by the negative pole. In the position *FF* the curve is flatter, but the brightest rays, at an angle of 40deg., are only partially utilised, as they fall at an angle on the surface. In the position *F<sub>1</sub> F<sub>1</sub>* there is a more intense illumination, but the curve is deeper.

For these reasons the ordinary arc lamp is but little fitted for printing. The position of the crater constantly changes, so that the illumination is uncertain. An alternating current lamp is much better, as flat craters are formed on both carbons, which radiate

Fig. 6.

the light equally upwards and downwards. The output of light is, however, small, for this lamp gives scarcely half the light of a continuous current lamp for the same amount of current. For these reasons these lamps are not suitable for printing.

The almost invisible arc emits principally the ultra-violet rays, which, however, are of scarcely any importance in printing, as they are almost completely absorbed by the glass. With the size of the lamps or the strength of the current, the length of the arc increases, and therefore also the quantity of the ultra-violet rays, as is shown by the following experiment: In the most intense rays of an 8 ft. 24 ampere lamp, at a distance of 20in., a strip of collodion paper was exposed till of the same depth as its "tint." The following times were required:—

8-ampere .....	364 seconds.
24-ampere .....	56 seconds.

Strips of the paper were then covered with a sheet of as colourless glass as possible  $\frac{1}{4}$  in. thick, and exposed under otherwise similar conditions. The following were the times of blackening:—

8-ampere .....	423 seconds.
24-ampere .....	87 seconds.

From these numbers it is obvious that the light of the small lamp contained only 14 per cent. of ultra-violet, which was absorbed by the glass, whilst the large lamp contained 30 per cent.

A part of the rays emitted by the arc—obviously the ultra-violet—are received after passing through the glass, a fact which explains the extraordinary superiority of the large lamps, for the increase of the current to three times has raised the photo-chemical power

"The Manufacture of Light." By Silvanus P. Thompson. 1906. Page 41.

x and a half times, or, if the ultra-violet rays are not considered, five times. The brightness of the light increases very quickly with the increase of current, but not in strict proportion.

From the above figures we may also conclude that with the small lamps, at 20in. distance, about four times as long is required to print as with diffused daylight, whereas with the large lamps the time is somewhat less.

A sheet of collodion paper, in the position *FF'* (Fig. 7), at a distance of 10in., gave an oval of about 84 square inches in area. The printing frame should always be placed with its longer side parallel to the axis of the lamp, and several frames should be used once so as to use up the whole of the rays emitted. The use of reflectors to concentrate the light upon one frame is, as has already been pointed out, of but small value. An experiment with a white enamelled, half-cylinder reflector proved that the time of exposure was shortened only 10 to 15 per cent.

The above figures also show that the use of several lamps to

Fig. 7.

obtain equal illumination over a larger field is very extravagant, or with three small lamps of 8 amperes only half the action of one 4-ampere lamp is obtained.

A searchlight will, as has been stated, give a more extended field, but a much simpler arrangement consists of a white, cone-shaped reflector, with rounded bottom, in which the carbons are placed horizontally and with the crater turned away from the mouth, as shown in Fig. 8. Lamps of this kind have been used for years in the Imperial Military Institute at Vienna. The lamp is run with 100 amperes, and gives, at a distance of 40in. from the poles, a perfectly homogeneous field of 46in. diameter. In spite of the amount of current used, it is not so extravagant, as will be seen from what follows.

With the same current, four lamps of 25 amperes could be run, of which each, at a distance of 10in., will blacken about 84 square inches of paper, and at a distance of one yard, sixteen times this area, or 1,340 square inches. With four lamps, therefore, about 200 square inches can be printed. With the 100-ampere lamp a circle of 46in. diameter is covered, or about 110 square yards. With the 25-ampere lamp the blackening to standard, at a distance of 20in., takes 87 seconds; therefore, at a distance of 40in., 384 seconds. With the 100-ampere lamp, under similar conditions, the time was 95 seconds. If the time for the blackening be divided by

the area, we obtain the time required to blacken the area unit (one square yard)—that is, if all the rays are directed to the area.

We thus obtain for the four 25-ampere lamps,  $348 \div 384 = 0.91$  seconds, and for the 100-ampere lamp  $95 \div 110 = 0.86$  seconds. So that both arrangements are approximately the same as regards cost, and the four small lamps are only advantageous when their light is used on several sides.

Fig. 8.

It is interesting to note the large quantity of ultra-violet rays which the 100-ampere lamp emits. With the naked light the collodion paper blackened to the standard in 41 seconds; under similar conditions, with the interposition of a sheet of glass, 95 seconds was required. The light contains therefore, almost 60 per cent of ultra-violet rays, which are lost by printing through glass.

#### DEATH OF MR. JOHN A. HODGES.

Another well-known worker in the photographic world has passed away in the person of Mr. John A. Hodges, whose death took place at Ealing on October 25 at the early age of 46. Mr. Hodges was an enthusiastic and active photographic worker, and his writings, both in article and book form, bore the stamp of emanating from one thoroughly acquainted with his subject. He was also one of the most able exponents of the pictorial lantern-slide, of which he possessed a large collection, illustrating the most beautiful portions of English and Welsh scenery, and these, together with his services as lecturer, were for many years freely placed at the disposal of societies. Mr. Hodges for some years discharged the duties of hon. secretary of the Royal Photographic Society, and was a constant exhibitor at its exhibitions, and although for some time past various causes have prevented his taking an active or prominent part in photographic matters, his unfailing courtesy and ready help will long be remembered by those with whom he was for many years associated. We tender our sincere sympathy to Mrs. Hodges in her bereavement.

**AIDS FOR THE ARTIST: HOW TO IMITATE THE BEST JAPANESE PAINTERS.**—Some knotty lines (trees); congested sky and vernal earth; two or three chance splashes (birds); one or two diagonal-eyed figures of uncertain sex; name the mixture "Garden Scene in Tokio."—From the "Globe."

**HOUGHTON'S QUARTERLY.**—The current issue of Messrs. Houghton's gratuitous publication for amateur photographers is largely occupied with a demonstration of the optical qualities of the "Ensign" Anastigmat. This takes the form of a series of photographs by Mr. H. W. Bennett, who, as an expert in architectural photography, may most certainly be regarded as a conscientious worker not predisposed to take a roseate view of his optical tools. Mr. Bennett reports most favourably on the "Ensign" Anastigmat, and in proof of his statements permits Messrs. Houghton to reproduce several photographs of difficult subjects taken with the lens listed for a plate a size smaller than that actually used. A copy of the "Quarterly" may certainly be recommended to those anxious to take advantage of Messrs. Houghton's offer of the lens at a reduced price—an offer which remains open until November 30.

## ENLARGED NEGATIVES DIRECT.

(From the Journal of the Birmingham Photographic Society.)

Owing to the distressing loss of quality in enlarged negatives made from a small transparency, I have for some time been experimenting with several methods of reversal. Members who have used the Autochrome process may have tried the method of producing a positive from a negative set out in Messrs. Lumière's instructions for that process, and if so they will have found that it does not work satisfactorily with ordinary plates, probably owing to the coating being much thicker than that employed on the Autochrome plate.

However, here is a method published by M. Balagny, which I have used with complete success, both for plates and negative paper.

The original negative is enlarged on to an ordinary slow plate, and developed with—

A. Amidol .....	15 grs.
Sodium sulphite .....	80 grs.
Ammonium bromide 10 per cent. ....	2 drs.
Potass metabisulphite .....	5 grs.
Water .....	5 ozs.

Development is stopped when the image shows through at the back of the plate.

Assuming a good positive has been obtained, it is washed for five minutes, backed with a piece of wet black paper to prevent halation, and exposed to daylight for 30 seconds, or 6 inches of magnesium ribbon is burnt one foot from the plate.

All subsequent operations are conducted in the dark-room, in a good yellow light. After exposure the plate is bleached in—

B. Potass bichromate .....	75 grs.
Nitric acid .....	30 minims.
Water .....	5 ozs.

and after the action is complete immersed in—

C. Sodium sulphite .....	1 oz.
Potass metabisulphite .....	15 grs.
Water .....	5 ozs.

This solution will clear the bichromate stain from the film in about five minutes, when the plate is well washed and redeveloped in—

D. Amidol .....	15 grs.
Sodium sulphite .....	80 grs.
Potass metabisulphite .....	15 grs.
Water .....	5 ozs.

till the image is black enough, and, finally, it is fixed and washed in the usual way.

CECIL R. M. PARR.

**CHRISTMAS POSTING.**—Messrs. Raines and Co., of Ealing, present to photographers in this issue a table of times for the posting of letters and book packets in time to reach practically any part of the world by Christmas or New Year. The table should be of value to our professional readers in enabling them to observe punctuality in the supply of photographs to be sent abroad; it should also suggest the advisability of looking after business of this kind.

**THE AUTOCHROME PROCESS IN AMERICA.**—For Mr. Alfred Stieglitz's tireless energy the Autochrome process—so we see from the current issue of "Camera Work"—has provided a new channel. For several months of the past summer Mr. Stieglitz has been in Europe, where, with Mr. Steichen and Mr. Frank Eugene—both staunch photo-secessionists—he has prepared a collection of Autochrome transparencies. Within forty-eight hours of landing in New York he had issued a letter to the American Press, inviting them to visit an exhibition of these Autochromes at the "Photo-Secession" Little Galleries. In "Camera Work," No. 22, Mr. Stieglitz is surely guilty of letting the cat out of the bag when he explains that it was Mr. Steichen who gave the cue to a certain photographic journal as to the possibilities in the process. The cue, says Mr. Stieglitz, was taken, and the result—we quote Mr. Stieglitz—was a journalistic "flare of trumpets." We are glad to learn that a special supplement to "Camera Work," dealing with the Autochrome process, is in preparation. It may describe certain new practice of the process worked out by Mr. Frank Eugene, and will contain reproductions of Mr. Steichen's Autochromes of Lady Hamilton, Mr. Bernard Shaw, Mrs. Alfred Stieglitz, and a portrait group taken on Mr. George Davison's house boat. Mr. Stieglitz is not the man to turn back from a task until he has spent all his might on its highest accomplishment, and therefore this special issue of "Camera Work" should be of unusual interest. We ought to say that it is obtainable only from Mr. Stieglitz, at 1,111, Madison Avenue, price 18s. the single copy.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between October 21 and 26:

**CINEMATOGRAPHS.**—No. 23,396. Improved cinematograph apparatus. Thomas Walter Barber, 82, Victoria Street, Westminster, London.

**VIEWING APPARATUS.**—No. 23,478. Improvements in the form of apparatus for viewing photographic and other transparent daylight and artificial light. Crossley St. John Broadbent, Railway Road, Darwen.

**COLOUR PHOTOGRAPHY.**—No. 23,615. Improvements in colour photography. Edgar Clifton and Arthur Ernest Wells, 1, 1, 1, Street Buildings, Liverpool Street, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**LENSES.**—No. 17,624, 1907. The claim is for a spherically and optically corrected objective with astigmatic flatness of picture, consisting of four lenses of two kinds of glass, two of which, a double convex and a double concave lens, are cemented together and are arranged before the diaphragm; the two of a negative and a positive meniscus separated by an air space being arranged behind the diaphragm, the positive lens having each time a higher refraction and less dispersion than the negative. Rudolf Steinheil, 17, Theresien Höhe, Munich.

**DEVELOPING TANK AND DIPPERS.**—No. 21,975, 1906. The claim is a vessel provided with ledges, *b b*, in which rest plate-holders of the form shown in fig. 2. The holder has projections, *i i*, which rest on the ledge *b*, and allow of a slight motion

Fig. 1.

Fig. 2.

imparted to the plate. In fig. 2 the plate is slipped into grooves, *i i*, and the dipper is removed by the handle *g*. William Laurence Parkinson, of 3a, Imperial Chambers, Dale Street, Liverpool.

**FOCUSING.**—No. 22,238, 1906. The invention consists in a method of focussing, not by observing the sharpness of an image on a screen, but by observing the coincidence of two (divided) images of an image.

As shown in figures 1 and 2, there are fixed at the top of camera two small concave mirrors I and II of a diameter of 2 centimetres, and approximately in the plane of the sensitive plate. They are fixed on one common narrow strip or slit *X*, which is upright when the mechanism is in use, and may be turned down on the camera when the mechanism is not in use. These mirrors are of approximately equal focal lengths with the lens of the apparatus. There is arranged on a level therewith a third concave mirror III of about 4 centimetres in diameter which is secured to the lens and moves therewith towards the sensitive plate and towards the mirrors I and II. This third mirror comprises two halves, a top and bottom one, which are capable of relative motion on a vertical axis, so that one half is parallel to the mirror I, and the other half is parallel to mirror II. The focal length of these two semi-mirrors is about one-half of that of the lens of the camera. The mirror III

attached to an arm Y (figure 2) which, when not used, may be turned down in front of the lens.

An observer viewing the mirror III from O (figure 1) sees in the top-half of the mirror III the image of the objects projected thereon from I, and in the bottom half the image projected thereon from II. The mirror III is arranged at such a distance from the mirrors I and II that when focussing the camera for an infinite distance an infinitely remote perpendicular line appears to run continuously in the top and bottom halves of the mirror III. Each less distant perpendicular line appears, however, to be broken off, and the two halves are wider apart the closer the object is. If, however, the lens is placed farther from the sensitive plate, and at the same time the mirror III, from the mirrors

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 5.

Fig. 4.

I and II, an infinitely remote perpendicular line will now appear to be broken off, whilst the image of a nearer positioned perpendicular line is continuous. The coincidence of the two images of the same object always takes place, provided that the device is accurately adjusted, when the image is simultaneously sharply focussed on the opaque plate. That which applies to perpendicular lines also applies to any other line which intersects the dividing line in the middle of the mirror III, except that the relative displacement of the two line portions is not so great. Focussing is not possible on lines which run parallel with the dividing line on III, as such lines only appear to run into each other. If an object only consists of horizontal lines, the camera would have to be turned somewhat in order to be able to focus with the mechanism. Figure 3 shows the focussing of three differently remote trees. The apparatus is in focus for the tree 2, while the tree 1 is in front of, and the tree 3 behind the accurately focussed tree.

The focussing of an object is effected in a very simple manner in that the lens is screwed until the object to be photographed appears continuous on the top and bottom halves of the mirror III.

The conditions for the proper function of the described arrangement are clear from figure 4, which represents a diagrammatical horizontal section through the half of the focussing mechanism.

The observer B looks in the direction of the optical axis B C on the concave mirror III. The inclination of this mirror towards the optical axis is arbitrary; it may be assumed that the line A<sup>1</sup> A which is perpendicular to the surface of the mirror forms with the optical axis the angle  $\alpha$ . The effect of the mirror can be assumed as replaced by that of the plane mirror E F perpendicular on A<sup>1</sup> A; in this case the concave mirror serves only to magnify the field of sight. A perpendicular lying on the optical axis is then viewed as running continuously from B, when it again appears on the optical axis after double reflection on mirrors I and III. It may be assumed that this condition should be fulfilled for the two extreme points, namely, for the focussing of  $\infty$  and for the nearest point for which the focussing shall be efficient; the last-named point may be positioned at C. Be it assumed that C is remote from the lens to the extent of  $n f$ , that is  $n$  focal lengths from the lens. The mirror III assumes the position E<sup>1</sup> D F<sup>1</sup> when focussing the lens on C. In this instance the distance

A D =  $a$  is equal to  $\frac{1}{n-1} f$ . In order that the focussing for  $\infty$

may be accurate, the ray B A, which is reflected to A G, must be reflected from mirror I to K, so that K G is parallel to C B. K G will then be reflected to G A and to A B. It follows therefrom that  $\angle K G A = \angle G A J = 2\alpha$ ; and G O the bisecting line of the angle K G A, perpendicular on the mirror I at the point G and H J, the tangent on the concave mirror I at G. If A J =  $b$ , G A =  $b$  as triangle, G A A<sup>1</sup> is in congruity with J A A<sup>1</sup>, and also A O = A G =  $b$ . After the displacement of the mirror III to E<sup>1</sup> D F<sup>1</sup>, the ray B D is reflected to D L, so that D L is parallel to A G. D L is reflected from mirror I to L Q. L Q intersects G K at P. The extension of P Q must meet C; if this is the case then also the ray emitted from C after the reflection at L and D has the direction D B. As A G and D L are parallel rays, they intersect after the reflection on the concave mirror I at the focal point of the latter. Therefore P G = the focal length of the concave mirror I, which may be designated  $e$ . If L G =  $c$  and G J =  $d$ , one has  $a : b = c : d$  because the triangles, G A J and L J D, are similar to each other. Further, if P R is drawn parallel to H J, and R C is marked  $l$ , in the similar triangles L G P and P R C :  $c : d = e : l$ , from this results:  $a : b = e : l$  or  $a : l = b : e$ . On assuming that

$l = C A = 10f$ , then  $a = \frac{1}{9} f$ ,  $a : l = \frac{1}{9} f^2$ . Therefore for

the points between  $\infty$  and C, the condition that the focussing is correct is  $b : e = \frac{10}{9} f^2$ .

Strictly speaking, the focussing is not accurate for all points located between C and  $\infty$ , because the focal point of the concave mirror I and the front focal point of the lens do not coincide with each other. The difference with respect to the accurate focussing is, however, always so slight that it does not exceed

the value of  $\frac{1}{250} f$ , and is therefore of no practical importance

in the case where the distance of the objects to be focussed is not less than about nine times the focal distance, which is quite sufficient for hand cameras. The focal length of I should be approximately equivalent to that of the lens, so that the image appears in the same reduction as on the plate.

The whole focussing system may also be carried out in such a manner that prismatic convex lenses are employed instead of the inclined concave mirrors. The two image forming lenses must then be in the plane of the lens, and the divided lenses uniting the image in the plane of the sensitive plate. This construction is somewhat more awkward than that with concave

mirrors, but has the advantage that it yields accurate results for all ranges provided that the front focal points of the focussing lenses are located with that of the lens or object glass of the camera in the same plane perpendicular to the optic axis.

If it is not necessary to focus the image when the holder of the photographic plate is inserted in the camera, for instance, in larger stand cameras, the two image-producing lenses I and II (figure 5) may also be arranged directly against the lens or object glass, and the lens III, taking up the image, may be substituted for the opaque glass plate. The lenses I and II must then, of course, be covered for photographing. Dr. Walther Thorner, 118, Wilhelmstrasse, Berlin.

**PHOTOGRAPHS ON GLASS AND PORCELAIN, ETC.**—No. 1,928, 1907. The invention relates to a process of preparing ceramic enamels. A support is covered with a layer of bichromated fish-glue, the dried layer exposed under a negative, developed, hardened with a tanning agent, and fixed.

The developed image is treated, prior to fixing, with a solution of hydroquinone, which causes a deep black coloration of the image on fixing, when the tanned image is dipped for some time in a solution of logwood extract. The same effect is obtained by dipping the developed image for some time in a mixture of the hydroquinone solution and logwood extract.

It is well known that it is necessary to mix the chromatised fish-glue with a saccharine substance in order to prevent it from becoming brittle on fixing. As such saccharine substance, a concentrated decoction of malt, such as a dark beer rich in malt, is preferred, as malt has proved to give a high degree of tenacity to the bichromated fish-glue when a mixture of both is exposed to the action of heat.

A solution is prepared composed of 400 ccs. fish-glue, 40 to 60 gms. of bichromate of ammonium, and 700 ccs. of dark beer which is rich in malt. The support of metal, glass, or porcelain is covered with a layer of the above solution, and dried preferably by means of "a centrifugal."

After drying the support is placed with its sensitive layer under the negative, exposed, and after exposure washed with water to develop the image. After development the support, with the image adhering thereto, is placed in a tanning bath consisting of an aqueous solution of from 5 to 10 per cent. of hydroquinone. Finally the support and adhering tanned image are fired in a closed furnace (muffle, covered hearth and the like), as by this way a more uniform and a more brilliant black is obtained than by firing on an open fire. Alfred Hans, No. 14, Rubensstrasse, Friedenau, near Berlin.

**CHANGING BOXES.**—No. 480, 1907. The invention consists of a changing box comprising an inner and outer case, slotted guides, pin-supported sheaths, extractor and springs, stop-blocks, spring-stops, removable door, dummy sheath and flexible shutter, in which all "plates" but one are drawn out, as described with the aid of eighteen diagrams in the specification. George Russell Nicholls, 48, Crescent Road, South Norwood Park, S.E.

**REFLEX CAMERA HOOD.**—No. 2,912, 1907. The claim is for a hood or box-like casing comprising a top wall which is adapted to be connected by a hinge to the camera box, opposite side walls, an end wall provided with a sight opening, and a bottom wall connected by a hinge to the end wall, and light-excluding means connected with the opposite edges of the bottom wall, movable therewith when the bottom wall is swung relatively to the end wall, and applicable to exclude light from opposite side spaces between the side walls and the bottom wall. Julius Daniel Garfield, No. 26, Beech Street, Springfield, Massachusetts, U.S.A., and Charles Bauer Harris, 39, Madison Avenue, Springfield.

**CAMERA STAND.**—No. 12,481, 1907. The invention consists of the combination with a camera tripod of a detachable socket, with telescopic tubes and rods, clamping means to the sockets and tubes, and means such as feather and groove to prevent the rotation of the telescopic tubes. Edmund Healiss Harrison, 282, Croxted Road, Herne Hill, London, S.E.

## New Trade Names.

**PUREX.**—No. 296,271. Chemical substances used in manufactures, photography or philosophical research, and anti-corrosives. James Ballantyne Hannay, Greenford Colour Works, Greenford Road, Greenford Green, Harrow, Middlesex, Manufacturing Chemist. Sept. 12, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Lighting the Portrait.

In arranging the lighting to suit the individuality of the sitter (writes Mr. A. J. Anderson in an excellent series of articles in "The Amateur Photographer"), I can only suggest two general principles: a strong, masterful face demands, as a rule, a somewhat strong scheme of lighting. A strong scheme of lighting is usually obtained by blocking up part of the window, or otherwise concentrating the light; a soft scheme of lighting may be obtained by placing the sitter at some distance from the window and fairly close to the reflecting screen, or by breaking and softening the light with a thin muslin curtain hung across the window. But a strong scheme of lighting should be followed by a generous exposure, and a somewhat short development in a diluted developer, lest the contrasts should be crude and coarse; and a soft scheme of lighting requires more vigorous development in order to obtain sufficient strength in the high lights. If the sitter has a sloppy character, shown by a slack mouth, and a chin that might have been carved out of a turnip with one sweep of the knife, the case is hopeless; but if the sitter has a well-formed character, each little depression and ridge and modelling on the chin, cheek and forehead means something, and the photographer should not be content until he has found a lighting that will bring out this modelling. With personal friends the habit of observation will enable us to notice some position, some lighting, in which both pose and lighting bring out the best and most characteristic qualities of their features, and they can often be photographed in the identical position; but with strangers, only practice and the seeing eye, combined with intuition, will empower us to depict character. Above all things, the portrait photographer must learn to see shading on a face, and this is quite an acquired power.

## New Books.

"Camera Work," No. XX. New York: Alfred Stieglitz. 4dols.

Our luxurious American contemporary sounds and sustains a triumphant note in its twentieth issue. It sings the praise of photography; the praise of colour work and the Autochrome essays of Messrs. Steichen, Stieglitz, Eugene, and others; praise of Lumière and of Bayley; praise of the Columbia University, which has "recognised" pictorial photography; and of Mr. Clarence H. White, who is to lecture upon it; and, finally, praise in *excellis* of Mrs. Käsebier. It ends, however, upon a melancholy and despairing note directed towards journalistic criticism generally, when it is disposed not to join in the psalm. As a whole, the letterpress is scarcely up to the not over-exalted literary standard of previous numbers.

The ten plates, on the other hand, are no less fine than their fore-runners. Mr. George H. Seeley, who, by-the-by, comes in for a good share of the plentiful praise, has six plates of undoubted, but unequal, merit. We learn that he is young and new to the work and that great things are expected of him. This expectation of great things from newcomers is a doubtful policy, more often than not puffing up with a little brief importance a worker who might develop more safely and surely if he were not breathlessly watched. Whilst we accept Mr. Seeley's work as showing something of an individual purpose, we commend to him, at the same time, the second half of the creed of Mrs. Käsebier as given in these pages: "The artist must be on his guard against being led into artificial channels." The "guard" we may add, is seldom large or strong enough for the purpose. Mr. Seeley's "Firefly" has a decorative strength and beauty of tone that makes it the best of his plates here shown. It is a head wearing a coronet, a throat, and a hand holding the firefly, presumably. The rest of the accessories are beyond recognition by a commonplace Londoner. If photographers would only realise the gain of interest and strength that comes of having a "motive" in their compositions, they would escape much of the adversity so sorrowfully deplored by Mr. Keiley. The three plates by Mr. Stieglitz are strong upon that very account. They are not in the nature of a silly puzzle that is not worth puzzling over. They delight because they are sane and ordinary representations of city life, holding a beauty that escapes the man in the

street. To our minds the Berlin view is by far the best, both photographically and artistically.

The remaining plate is a "Nude" by W. W. Renwick, and we can give it no higher recommendation than calling it one of the most successful nudes we have ever seen which were not produced by the hand of a Frenchman. Grace of line and delicacy of tones could hardly be better secured. The pose recalls that of the so-called "Venus" of the so-called Velasquez, and for the thousandth time shows up the error of the pelvic line in that most patent fraud.

"LOUIS WAIN'S ANNUAL."—We know many persons who regard Mr. Louis Wain's Annual as the most humorous of the Christmas publications. This year Messrs. Bemrose and Sons, Limited, greatly add to the attractiveness of the volume by the lavish use of three-colour supplements. The volume, moreover, contains an excellent literary programme, and is wonderful value for 1s.

## Dew Apparatus, &c.

Printing Framework and Diffusing Screen for Use with Enclosed Arcs. Made by the Westminster Engineering Co., Ltd., Victoria Road, Willesden Junction, N.W.

The "Westminster" enclosed arc lamps have been noticed already in our pages, and must be sufficiently well known to many of our readers to render unnecessary any lengthy reference to them. Moreover, the list of the Westminster Engineering Co. describes them

fully, and a number of the results obtained by them in the regular way of business may be seen in the present exhibition at our offices. One may, however, draw attention to two accessories which are of recent introduction on the part of the Westminster Co., and extend or facilitate the employment of the lamps. The first is a cast-iron framework for the support of printing frames. The frame, as shown in the figure, is seven-sided, and is painted white inside. It accommodates 48 half-plate printing-frames and 8 whole-plates during printing, the lamp, of course, being caused to transverse the height of the framework in small stages or with a slow continuous motion up and down. The stands on which the lamps are counterpoised permit of this being readily done by the printer. The price of the frame is £4 5s. Carriage and packing, if four frames are ordered, are free throughout the United Kingdom.

The second accessory—a diffusion screen—scarcely requires any comment, beyond the reference to the drawing of it. It is sold at £1 5s.

The "Goergen" "Central" Shutter. Sold by J. H. Dallmeyer, Ltd., 25, Newman Street, Oxford Street, London, W.

Despite the great number of shutters on the market, there must, nevertheless, be a demand for exposing apparatus of a special, even of a limited, character, which is all the more useful from the fact that its powers are not all-comprehensive. The "Goergen" shutter is one of these. It has a sphere of use quite its own, and one in which it fulfils its prescribed duties most efficiently. It is essentially

a shutter for time-exposures, and is used in either of two ways—by hand (for long-time exposures), or by pneumatic bulb for those of shorter duration. In the first case the leaves of the diaphragmatic plate are turned back by moving the milled head V, and the aperture is closed by a reverse movement. In the second case, the V-mark is turned to Z, and pressure on the bulb then opens the shutter, which does not close until pressure is relaxed. As regards ability to keep open for any length of time, Method II. seems to be limited only by one's patience, but for exposures of more than thirty seconds, the hand opening and closing is, of course, the more convenient. The shutter works practically silently, with no more noise than a smooth pen makes in a writer's hand. Hence the larger sizes should be very excellent studio shutters. The flat build of the shutter renders it a very convenient accessory to a focal-plane camera; it can be carried easily as an extra shutter and used on many occasions when a focal-plane shutter, from the noise and vibration which it produces, may be useless. The "Goergen," it should be explained, is of the "ever-set" pattern, and while we have emphasised its convenience as a time instrument, we should not omit to mention that it is adjusted to give an instantaneous exposure of about 1/80 of a second, or longer if the bulb is pressed slowly. As an accessory shutter it is certainly a most convenient piece of apparatus. We can recommend it to users of reflex cameras, with which type of instrument a lens-shutter is a desideratum when using the camera on a light tripod. The "Goergen" is made for hoods from 1½ in. to 4 in., at prices from 14s. to 24s.

Cooke Series VI. Portrait Lens, and "Cooke" Convertible Anastigmat. Made by Taylor, Taylor, and Hobson, Stoughton Street Works, Leicester.

Since reviewing these two lenses, as the result of a visit to the trade section of the recent R.P.S. Exhibition, we have had an opportunity of submitting both of them to a practical examination, the results of which we may take the opportunity now of recording while re-stating in a few words the salient features of these two additions to the series. The convertible "Cooke" or "Twin" Cooke, as it has been referred to, consists of two "Cooke" anastigmatic triplets with an iris that can be mounted in front of either of the triplets or between the two. The separate triplets are of 14.2 and 21.2 inches, which, when combined, give a focal length of 8.6 inches, with an aperture of  $f/6.5$ . The separate triplets each have a full aperture of  $f/11$ . As regards the working of the objective, our tests indicate that it has all the well-known good qualities of the Cooke lens. The definition is very fine with each of the above focal lengths. With the 14.2 and 20.2 lenses, used with stop in front, there is a barely perceptible indication of distortion with the 14.2 lens, and slightly more with the 20.2, but the amount is very small. The 8.6 combination is very perfectly corrected, and shows no perceptible form of aberration on a half-plate, which is the size it covers. The Series VI. portrait lens is a variety of the well-known focussing "Cooke" lens, so arranged that by a system of cords and pulleys, the stops, and also the focus can be adjusted from the back of the camera. The focussing system is modified by the addition of a

series of numbered graduations on the focussing ring, and it is therefore possible to introduce and repeat any desired degree of diffusion, or want of focus, by turning the ring to any particular graduation. Our tests show that this lens is admirably suited to its purpose. Though listed for 1/1-plate at full aperture, it covers a 10 x 8 plate with excellent definition, and the diffusion produced by turning the focussing ring is very uniform. The tests were made on a 12 x 10 plate, and the lens covered even this size very satisfactorily.

The A.E.G. Nernst Projector Lamp. Sold by the A.E.G. English Manufacturing Company, Limited, 4, New Compton Street, Charing Cross Road, London, W.C.

In this new type of Nernst lamp a most ingenious electrical device is used to allow of very high candle-powers being obtained. The burner is fitted with a heating coil in conjunction with resistances of special construction, which intensify the current to 1.33 amperes and allow of 500 c.p. being obtained per filament—that is to say, the total consumption for the three filaments is but 4 amperes. On this basis the makers have drawn up the following table of candle-powers obtainable with different voltages:—

100 volts= 600 c.p.	220 volts=1,400 c.p.
110 volts= 700 c.p.	230 volts=1,500 c.p.
200 volts=1,200 c.p.	240 volts=1,600 c.p.
210 volts=1,300 c.p.	250 volts=1,700 c.p.

The lamp is supplied for direct or alternating current at voltages of from 100 to 300, a burner suitable to the voltage being inserted instantly on the projecting pins attached to the centre plate of the lamp. The lamp is so small—about 8 by 4½ by 6 inches—that it will go into any lantern, and as the light remains quite constant after having attained its maximum two minutes after switching on, the new instrument ought to find great favour with enlargers, lantern exhibitors, and others. It is sold complete, with two spare burners for any voltage, at £3 18s.

**SOUTH LONDON EXHIBITION.**—The next exhibition of the South London Photographic Society will be held at the Art Gallery, Peckham Road, S.E., from March 7 to 21 inclusive. The hon. sec. is Mr. Edward Pady, 260, Southampton Street, Camberwell, S.E., to whom all inquiries respecting the exhibition should be addressed.

**THE SCOTTISH SALON.**—The next Scottish Salon is to be held in Aberdeen in February next. Like its predecessors it is to be open to the works of photographers (professional or amateur) resident in Scotland, also the works of Scotsmen not resident in Scotland, of whom there are a very large number in London alone, some of whom it is hoped may be able to send work to Aberdeen. In addition to purely Scottish work, the President of the Royal Photographic Society, Mr. J. C. S. Mummery, has very kindly accepted the committee's invitation to send an exhibit representative of English work, and Mr. Henry J. Comley, the secretary of the Society of Colour Photographers, is arranging a special exhibit of the latest developments of colour photography.

**THE ROYAL SOCIETY OF BRITISH ARTISTS.**—The 128th exhibition of this Society is not more interesting than its 127th, but there are many works that will fully sustain its recently improved reputation. The resident, Alfred East, Esq., A.R.A., does not send such ambitious and striking work this year, and the general diminution in the size of work seems to rob the show as a whole of some appearance of dignity. As large pictures do not sell readily in these days this change is perhaps expedient. The artists whose works stand out prominently are D. Murray Smith, who affects Corot-like designs; Spenlove-Spenlove, whose "River Bank, Walberswick," is homogeneous in its sunny effect; Alec. Carruthers Gould, a painter of whom the world is yet to hear much; F. H. Swinstead, a pastellist displaying unusual subtlety of observation; W. E. Schofield, the painter of grey wintry subjects of great truth; and J. W. Schofield, an accomplished water-colourist. Beyond these we should draw attention to F. O. Salisbury's little boy wearing regalia, and called "Ambition," and to the excellently observed London evening scenes by A. Talmage. Amongst the water colours we were particularly charmed with J. J. Alsop's "Night in Venice," and the never-failing clever suggestions of G. C. Haité. Figure subjects are few, and, with the exception of W. Bramley's "Young Gamekeeper," poor also.

## New Materials.

**Snow-white Satin Bromide Paper.** Made by John J. Griffin and Sons Ltd., Kingsway, London, W.C.

A new variety of the Snow-white bromide paper is this of Messrs. Griffins, with a surface something akin to that of the albumen paper giving prints of great clearness in the whites. The new variety of paper is satisfactorily amenable to the sulphide toning process and owing to its hardened surface is more than ordinarily free from the blister trouble which is not infrequently attendant upon this toning operation. The paper is sold at the usual prices.

**Teb and Primus Xmas Cards.** Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

Messrs. Butcher's list of the well-known "Teb" Christmas mount is extensively illustrated throughout its forty pages with half-ton blocks printed on art paper in such a way that short of actual sample the purchaser gets a very good idea of the numerous styles and designs, though not of the colours. These latter, in many instances, are quite the charm of the mounts, since the absence of ornamentation of the mount is frequently of more benefit to the photograph than

its presence to an acute degree. Messrs. Butcher number the mount they send us, so that we can refer in confirmation of our contents to one or two mounts which we can recommend for their restful and unobtrusive design. Thus No. 9,002 may be described "fawn" colour (sold also in green), has a linen-faced surface, blocked in gold, and neatly tied with ribbon. Quite in nice taste as is also No. 9,007, in white and gold, sold in quarter-plate size only, at 18s. per gross. No. 9,004 is a dark brown mount, blocked in gold with "A Greeting," quarter-plate, 15s. per gross, both upright

and oblong. A good mount for sepia-toned bromides. No. 9,013 is a pretty card for circle prints. It is "slashed," as the dressmaker says, with red ribbon under a gold motto, and is suitable for chalk carbons. Scottish cards and Dutch cards, and others, Greek Japanese in style, figure in Messrs. Butcher's variety, and, like others, are very moderately priced. The "Teb" list is certainly deserving of study, and the "Teb" cards are not unworthy of the choicest bits from one's season's negatives.

The "Auto-trans" Anti-frill Dish. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

Since announcing the ingenious appliance of the firm of Fallowfield, we have had the opportunity of satisfying ourselves as to the effective action of the dish. The illustration shows the construction of the dish. It is of the wooden glass-bottomed well type which

was not infrequently employed by wet collodion workers. Messrs. Fallowfield adapt it to the Autochrome plate by providing an inner frame, shown slightly raised in the drawing, which is faced with rubber on its lower side, and is pressed down on the film of the Autochrome plate by the turn buttons also seen in the figure. The penetration of the developer at the edges of the plate is therefore prevented, and all need of handling the Autochrome from first to last is obviated. The dish is certainly an acquisition to the new process, even though, as appears to be the case, the later batches of plates are as immune from frilling trouble as those obtained in the early part of July. The sizes and prices of the plates are as follows:  $3\frac{1}{2}$  by  $5\frac{1}{2}$ , 3s. each;  $4\frac{1}{2}$  by  $3\frac{1}{2}$ , 3s.; 9cm. by 12cm., 3s. 9d.; 5 by 4, 4s.;  $6\frac{1}{2}$  by  $4\frac{1}{2}$ , 4s. 9d.; 13cm. by 18cm., 5s.;  $8\frac{1}{2}$  by  $6\frac{1}{2}$ , 6s. 9d.

**CHRISTMAS POSTCARDS.**—Messrs. John J. Griffin and Sons are introducing a series of postal cards with Christmas mottoes in the various brands of paper made by them, namely, Goldona, P.O.P. and Bromide, as well as in their "Satin" bromide just introduced.

**"SWIFLEX" PLATES.**—The Halifax Photographic Co., Halifax, send us samples of their extreme-rapidity dry-plate sold as "Swiflex," a title which is not belied by the very high speed of the plates. The plates work clearly in the makers' developer of pyro-soda, containing one-sixth of a grain of bromide per ounce, and give negatives of good vigour and gradation. Prices of the plates and discounts applying to them should be obtained from the Company direct, at the address given above.

## CATALOGUES AND TRADE NOTICES.

**THE GRAFLEX CAMERA.**—Two most attractive booklets, illustrating the work of the "Graflex" (reflex) camera, of Kodak, Ltd., reach our table, and interest us, to commence with, from the reproduction of one or two of Mr. Alfred Stieglitz's photographs, taken with the Graflex. The booklets are worth getting by anyone who is curious to see the many-sided advantages of the reflex camera.

**BARNET SHOWCARDS.**—Messrs. Elliott and Sons, Ltd., show a fine sense of decorative effect in the advertising matter of the window-bill order which they issue to the photographic dealers. A selection of the showcards specially for the winter season affords us the opportunity of congratulating them on the effective use of photography as a stimulant of photographic trade, in the present instance of Barnet bromide and gaslight papers. Dealers ought not to omit applying for the cards, which are obtainable free.

**PROFESSIONAL SPECIALTIES.**—Messrs. F. E. Jones and Co., 22, Gray's Inn Road, W.C., send us a list of studio and other items of special interest to the profession. One line of the firm is art canvas for showcases and backgrounds. The list is sent free on application.

**THE ARTIFICIAL LIGHT EXHIBITION.**—Messrs. Fallowfield write that visitors to the exhibition interested in the Schroeder flash lamp are invited to inspect the apparatus at 146, Charing Cross Road, where a fairly large stock is held.

**ETON PHOTOGRAPHIC RECORD.**—With a view to preserving an interesting school record, it is proposed that every boy at Eton shall be photographed, and the captains of the school have issued an appeal to that effect. New boys and those who are leaving at Christmas are urged to be photographed as soon as possible.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 8.

Aberdeen Photographic Association. "The Rendering of Colour in Monochrome." Jas. A. H. Hector.  
West London Photographic Society. "Enlarged Negative Making on Glass and Paper." Jas. Brown.  
Manchester Amateur Photographic Society. "Snow and Sunshine in the Bernese Oberland." S. L. Coulthurst.

SATURDAY, NOVEMBER 9

Aberdeen Photo Art Club. Members' Lantern Evening.  
Manchester Amateur Photographic Society. "A Dive into Belgium." W. L. F. Wastell, F.R.P.S.

MONDAY, NOVEMBER 11.

Bradford Photographic Society. "Platinotype—Elementary, Glycerine Process, and After Treatment." W. E. Fearnley.  
Kidderminster and District Photographic Society. Amateur Photographer Prize Slides.  
Gravesend and District Photographic Society. "Flower Photography." E. Seymour.  
Scarborough and District Photographic Society. "Holy Days and Fête Days in Spain." E. F. Jameson.  
Oxford Camera Club. "Rotary Carbograph Paper."

TUESDAY, NOVEMBER 12.

Royal Photographic Society. "Discussion Upon the Best Methods of Advancing the Study of Photography in Colours."  
Rugby Photographic Society. Exhibition in the Benn Buildings, Rugby.  
Leeds Photographic Society. Siena, San Gimignano, and other Medieval Cities of Tuscany." Thos. E. Green.  
Epsom and District Literary and Scientific Society. "Ilford Plates." Algernon Brooker.  
Cardiff Windsor Photographic Society. "Tabloid Photographic Chemicals."  
Worthing Camera Club. "How the Saints came to Brittany." Mrs. Gostling.  
Birmingham Photographic Society. "Rotary Carbograph Paper."

WEDNESDAY, NOVEMBER 13.

North Middlesex Photographic Society. Sale of Photographic Apparatus and Sundries.  
South Suburban Photographic Society. "Flower Photography." E. Seymour.  
Leeds Camera Club. "Mounts and Mounting." Lionel Dickinson.  
Croydon Camera Club. Conversational Meeting.  
Everton Camera Club. "Glimpses of Wales." E. Youds.  
Borough Polytechnic Photographic Society. 1907 Affiliation Competition Prize Slides.  
Coventry Photographic Club. "Rotary Carbograph Paper."

THURSDAY, NOVEMBER 14.

Rienheim Club. "A Chat about Morocco." Charles Rosher.  
Ricmond Camera Club. "Flower Photography." E. Seymour.  
North London Photographic Society. "Holiday Sketches."  
Hull Photographic Society. "Three Colour Photography and Specimens of Autochrome Work." Henry J. Comley.  
Liverpool Amateur Photographic Association. "Natural History Photography." Geo. A. Booth.  
Hawthornthwaite Photographic Society. "Carbograph, the New Enlarging Carbon Tissue." Rotary Photographic Co.  
Lingston and District Photographic Society. "Ozobrome." Rev. H. W. Dick.  
Queen's Park Amateur Photographic Association. "Faking and Dodging." Dan. Dunlop.  
Chelsea and District Photographic Society. Lantern Evening—Affiliated Competition Slides, 1906.  
Hawthornthwaite Photographic Society. "Rotary Carbograph Paper."  
London and Provincial Photographic Association. "Scaloids." Messrs. Johnson & Son.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 5, the president (Mr. J. C. S. Mummery) in the chair. The lecture hall was crowded to the utmost with an audience assembled to witness a demonstration of the new Autochrome plates by Mr. T. K. Grant, the British representative of M.M. Lumière. Mr. Grant, in opening his subject, said he could not deal in the time at his disposal with the theory of the process, nor could he attempt to discuss the many practical recommendations which had been made regarding the plates. All he could do was to explain and to demonstrate the practice which he himself in his own work had found the best. As regards exposure, he agreed in taking 14 Wynne or 2 Watkins as a rough guide for outdoor exposures, but it was not a sufficient means of judging the exposure—which had to be considered in relation to the subject, and was a matter of practice. The old rule of exposing for the shadows and letting the high-lights take care of themselves could not be applied to Autochrome plates in the majority of subjects. A compromise had to be made where the range of tones extended from sky to deep shadows, and the lecturer recommended as a general rule that exposure should be given for the sky and light portions, and the shadows allowed to come out as best they would. In the case of a subject which included no sky the old photographic rule might be said to hold good. The lecturer reminded Autochrome workers of the necessity for allowing for extension of camera in calculating the exposure for near objects. Also, when a small stop was used, such as  $f/32$ , he found it desirable to give a longer exposure than would be naturally

proportionate to that stop. He suggested an increase, over and above the time corresponding to the stop, of 50 per cent.

In developing the plates it was best to work entirely in the dark. He arranged three solutions on the working bench—one containing the pyro and water of the developer, the second containing the ammonia which was added at the last moment, and the third containing the reversing C solution.

Intensification was a part of the process which, in the lecturer's opinion, should never be omitted. It did not necessarily increase the density of the plate, but it did contribute to the brightness of the picture and appreciably brought out the colours.

Regarding the use of the H (neutral permanganate) solution, its action was to prevent dichroic fog. If not allowed to act long enough, this two-colour fog was liable to appear on the plates, but a second application of the H solution would remove it. The short washing—five minutes—of the plates had been questioned, but Mr. Grant said he had not yet heard of a case in which this period of washing had proved insufficient.

Replying to a large number of questions addressed, Mr. Grant stated that the formula he now used for the intensification was as follows:—

Pyro .....	3 gms.
Citric acid .....	6 gms.
Water .....	1,000 c.c.s.

This contained twice the quantity of citric acid advised by MM. Lumière, but it acted sufficiently rapidly. For drying the plates a whirler was a very useful accessory, as drops of adhering water were driven off the plate, which could then be laid aside and dried in about ten minutes.

Replying to a question as to frilling, Mr. Grant said he had used none of the special mixtures advised for edging the plates, for the reason that he had not found the need of them. In his own use of the plates he had not come across a single case of frilling.

Replying to a further question, he said that, so far as he gathered from the reports of others, the later batches of plates were less liable to frill than those first issued.

A celluloid varnish might be used, provided it was free from alcohol; in his own practice he used a gum dammar varnish thinned with benzole to about half strength. Mr. Beeson mentioned that Messrs. Sanger-Shepherd made a suitable celluloid varnish, and another speaker stated that the cristoid varnish of the Sandell Films Company was a suitable preparation. This, Mr. Grant said, was a celluloid preparation.

Asked why alcohol should be injurious in the varnish, but was used in the developer, Mr. Grant said that that had been found to be the best practice by MM. Lumière. There was actually no need to use alcohol in the first developer; distilled water might replace it. Mr. Grant then proceeded to go through the operations of developing and completing an Autochrome plate, and within the space of something less than half an hour the finished picture—a group of flowers—was projected upon the screen and proved to be an admirable example of the process. A number of Autochrome results were then shown on the screen, including examples by the lecturer, Mr. McIntosh, Mr. Child Bayley, and Mr. Armytage Sanders.

In some further discussion which followed a question was raised as to the copying of Autochromes. Mr. Grant said that the simplest method was to place the Autochrome picture and the sensitive Autochrome plate, both filter side outwards, in the dark slide of the camera; the lens was pointed to the sky, and the surface of the outer plate thus evenly illuminated. He stated that a number of the results which had been shown on the screen were copies from Autochrome negatives or positives.

**CROYDON CAMERA CLUB.**—Although the Leto-pigment process has been demonstrated in the past at the club, yet Mr. F. J. Terry contrived to give the subject fresh interest, not so much perhaps by the elucidation of new points of procedure, but by the way in which he re-dished it for the edification of all present. For those bitten with pictorial mania, and dissatisfied with mere transcripts of nature, rendered by lens and plate, the Leto-pigment process should undoubtedly appeal, owing to the amount of control exercisable. Personally, being of an open and generous nature, "faking" with him—more often than not—resulted in the print being ultimately and suitably framed by the contour of the dust-bin. Notwithstanding this, there was a "moth-and-candle" fascination in being able to

emphasise here, or suppress there, as occasion or eccentricity demanded. Mr. Terry proceeded to develop successfully several posed prints, using the lid of an old packing-case as an easel; developer consisted of a bay-rum spray, affixed to a bottle which obviously held something different to the plain water it then contained. Instead of using brushes, the lecturer—referring to prints—said he preferred to spray, next soak, and spray again. Should accidental over-exposure prevail, the water might usefully be made alkaline. Whilst the prints were being developed, several questions were asked and answered, during the course of which members in the immediate vicinity of the lecturer were much struck with the continuing action of the pneumatic bay-rum discharge. A cordial vote of thanks was accorded for a really elegant demonstration.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—At meeting on Thursday, October 31, 1907, Mr. F. C. Mote in chair, Mr. A. W. Green lectured upon and demonstrated the "printing process." He said: "A printing process which admits practically as much personal control as the painter can secure with his brush and palette, except as regards the actual drawing, which gives permanent and beautiful results, of which the technical details are readily and easily mastered, is surely an ideal one for the pictorial photographer's standpoint." Such was, in brief, his description of the oil-pigment process. The paper was coated with a prepared tough gelatine, sensitised in a 5 per cent. solution of bichromate for one minute and allowed to dry in the dark. It was then exposed under a negative until the brownish-yellow image was seen, very much like a platinum print, and then thoroughly washed for half an hour. The yellowish colour visible during this wash entirely disappeared when the print was ready to pigment "develop." For developing the print should be placed upon a support of moist blotters or linen, or upon a sheet of glass or other support, and the water upon its surface removed either by blotting off or with a linen cloth. One of the special brushes was then charged with a small quantity of pigment ink and applied evenly to the surface, with a motion as used in stippling or stencilling. The pigment would attach itself to the damp gelatine in proportion to the light action, and the image gradually grew stronger and stronger. After pigmenting the print was hung up by one corner to dry, which would take from four to eight hours, when any surface hairs could be removed with a soft cloth or needle point. Spottings, if required, could be done by thinning the pigment with Megilgum whilst if any high-lights were too dark they could be lightened with the aid of indiarubber.

Mr. Dawson asked if various colours could be used upon the same print. Mr. Green had seen prints where three to four colours had been used. He thought the process gave promise.

Mr. Stretton asked if it were possible to use the ordinary art colours, and Mr. Green replied, "Yes; but they were considered too coarse."

Mr. Dawson asked if a roller could be used. The reply given was that the roller had been given up as unsatisfactory, Mr. Dawson maintaining that one could obtain control by the use of the roller.

Mr. Dockree remarked that a roller could not give a point.

Mr. Teape, in moving a vote of thanks, said that the demonstration had been a most excellent one.

Mr. Green, in his reply, said that Messrs. Griffin would give assistance to those working the process.

**SOUTHAMPTON CAMERA CLUB.**—The members of the above attended in goodly numbers on Monday evening last to meet Mr. Henry Comley, secretary of the Society of Colour-Photographers, one of the very foremost of the three-colour workers of the day, who came to lecture to them on three-colour carbon and the Autochrome processes. Mr. Comley's lecture extended over three hours, and the interest was not only sustained over the period, but the members showed signs of great individual activity in clearing up points mentioned by the lecturer. In the three-colour carbon process Mr. Comley began at the very beginning, showing the necessity for the light-filters and the three negatives, pointed out that the negatives should be of the thin variety, that their combined density should not exceed the density of the normal negative. He advised very dilute developer as the ideal means of production. He described very fully the processes of sensitising pigmented films which the "Rotary" people produced, and recom-

mended ordinary methylated spirit as the medium for the bichromate of potassium or ammonia, one to eight per cent. of the former, or one to 10 per cent. of the latter, half spirit, half solution; the sensitising to be done as quickly as possible, and the films to be absolutely dry before use. In the matter of the exposure of the film, the rule laid down was that in concurrent exposure, when a faint image appeared on the yellow film, the blue film was normally exposed, that the yellow required about twice the blue, and the red three times. Rocking the developing dish was not recommended, because of danger to details of high-lights, and in the process of development the use of a 10 per cent. sodium hydrate bath for rendering pigment more amenable to treatment was recommended. Mr. Comley proceeded to show the registration of the three films in order—yellow, blue, red—and some extremely fine prints were produced under the eyes of the members. Subsequently, after replying to many questions, Mr. Comley produced some fine specimens of Autochrome transparencies, and then went on to refer to the Warner-Powrie process. Mr. Comley was very heartily thanked for his fine lecture.

## Commercial & Legal Intelligence.

**TRAVELLING PHOTOGRAPHERS.**—At Samford Petty Sessions last week, two smartly attired young men, who had the appearance of City clerks, were charged with obtaining 5s. from Fredk. Alexander by a false pretence, at Capel St. Mary, on September 21. They gave the names of John and George Havard, and described themselves as photographers, of Sudbury. It was shown that they had got payment in advance for a number of photographs alleged to have been taken by them, but never delivered. They were committed for trial.

**CANVASSING FRAUD IN SCOTLAND.**—A case of considerable importance to the public was heard in Dumbarton Sheriff Court last week, when Edward Riffkin, 97, George Street, Glasgow, trading as the St. George's Art Company, Glasgow, sued Lawrance Watt, 6, Taylor Street, Clydebank, for the sum of 7s. 6d., being the balance of an account of 10s. 6d. alleged to be due by the defender. Sheriff Blair reviewed the modus operandi of the prisoner, and commented severely on the methods adopted and the pressure exercised by the canvassers to obtain such order from females—a servant or dependent, not accustomed with business, to hand over a photograph on the representation that the enlargement would be a work of art and would cost nothing. The thing was a swindle from start to finish, he declared, and the sooner the public knew it the better. He assuaged the defender, with £1 of expenses.

## News and Notes.

**THE SOUTHERN EXHIBITIONS.**—Tuesday next, November 12, is the last day for sending entries to Mr. S. G. Kimber, Highfield, Southampton. Intending exhibitors should apply for forms without delay.

**"YOUR MONEY OR YOUR LIFE!"** hissed the masked man at Jones's bedside. "Awri," replied Jones, "put it on the mat." The man with the bullseye repeated his request, and Jones, that keen amateur photographer, awoke. "Don't move," began the stereoscopic house-breaker, with a menacing frown. "Stand perfectly still," said the pride of the Balls Pond Camera Club, "if I take you by flashlight now, he prize for the week ending November the —" But the robber was already tearing his clothes on the cut glass at the top of the wall of the kitchen-garden.—"The Globe."

**CRITERION COMPETITION.**—The awards in the current competition are as follows:—First prize (£1 1s.) to Mr. G. W. Dunn, Manchester; 2nd prize (10s. 6d.) to Mr. J. Pendlebury, Leeds; 3rd prize (5s.) to Miss Pitt, Bridgnorth. Ten consolation prizes of 2s. 6d. to Mr. Redfern (Bradford), Mr. Nicholls (London), Mr. Green (Colne), Mr. Smith (Northampton), Mr. Carter (Manchester), Mr. Parker (London), Mr. Mannings (Birmingham), Mr. Bolton (Hull), Mr. Thompson (Northampton), Mr. Lester (York).

**THE R.P.S. DINNER.**—The annual dinner of the Royal Photographic Society took place at the Holborn Restaurant on Wednesday last week, Mr. J. C. S. Mummery, A.R.I.B.A., presiding. The President was supported by Sir Joseph Swan (Vice-President), Mr. J.

Spiller (past-president), and Mr. Francis Ince, honorary solicitor. The President, in proposing the toast of the Royal Photographic Society, alluded to the recent annual exhibition of the Society, and to its section devoted to the Autochrome process of colour photography. Mr. Ince proposed the toast of "The Visitors," to which Mr. M. Arbuthnot replied. Mr. D. Cameron-Swan, in proposing the toast of the stewards, Mr. A. W. W. Bartlett and Mr. Leslie E. Clift, in whose hands the arrangements had been, expressed the thanks of the members to these gentlemen. Mr. Clift and Mr. Bartlett briefly responded. The musical programme was somewhat unequal in character, but a mention must be made of Mr. Wolseley Hutt's rendering of Henley's "Falmouth" and "Western Wind," to the music of Furley Lewis, who himself accompanied.

THE ACCOMPANYING ILLUSTRATION, taken from our contemporary, "The Australian Photographic Journal," shows a curious effect of double exposure, the plate having been exposed both horizontally and vertically. This is demonstrated by the fact that if the picture be

turned sideways the boy totally disappears and another face and outline of a figure become distinctly visible. Although cases of double exposure are of common occurrence, it is not often that the two exposures are so clearly defined as in the present instance.

**MESSES. MOWLL AND MORRISON**, the well-known Liverpool photographers, of Hardman Street and Arcade, Lord Street (Fellows of the Royal Photographic Society), have received a Royal Warrant appointing them photographers to the King.

**"WHILE OTHERS SLEEP."**—The advertisement of the "B.J." Almanac and other things which appeared under this title last week, has made us the recipient of a good many comments—some fit for publication. The office boy of one reader was heard to remark: "Gord lummy, glad I don't work there." It is reported that Lord Rosebery, on seeing the drawing, exclaimed:

"Would that I were at 24, W— St—,  
These sleepless hours would find their solace."

But some terrible misconceptions appear to exist as to the subject of the illustration. The triangular outline towards the right of the ground floor is identified by one correspondent as the Bass trade-mark. He is prepared to prove that behind the window screen a bar is thus localised. Other evidence, bespeaking minute observation, point to the same conclusion on the part of the writer. Telegraphic address: Saline, Croydon.

**THE NEW ENGLISH ART CLUB.**—The autumn exhibition of this club comprises 123 pictures. Of these, five are excellent, twenty-one are good, sixteen are bad, and five are execrable in our view. Three brilliant and astoundingly clever sketches by Sargent, who is not a member, and a picture each by von Glehn and Holmes, make up the excellent five. The execrable five are contributed by A. E. John, who upon this occasion out-Johns himself. Who, outside his own coterie, encourages Mr. John in the exhibition of these nursery scrawls, which are too wearisome to be even comic?

## Correspondence.

### THE R.P.S. DINNER.

To the Editors.

Gentlemen,—The R.P.S. is to be congratulated upon its most recent development of means for attracting new members. Its dinner was excellent, and the musical artistes, in one case, at any rate, showed studied irresistibility. With such allurements, surely the crush of new members "couldn't get in at the door," to use the lady's own phrase.

The inclusion in the programme of "Onaway! Awake, Beloved!" has put into my head some jingle, *à la* Longfellow, upon this incident:—

Then came Ruby, the green-skirted,  
Pink of cheek, with postcard dentals;  
Sang of love, of swinging higher,  
Sang of dancing and of garments;  
Held her arms out to the men-folk;  
Held them out to the officials,  
Whilst her smile grew wide and wider,  
And the grey-beards dropped their eyelids,  
Head aside she gazed at Stuart;  
Called aloud the name of Houghton;  
In her dark eyes flashed the high-lights  
As the glint upon the bottles.  
Reaching forward sweetly, boldly,  
Sang she loudly, sang in this wise:  
"McIntosh! awake, Beloved!  
Thou the wild bird of the Squaire!  
Thou, with shirt-front powdered fawn-like!  
Does not all the blood within thee  
Leap to meet me, leap to meet me!"

And so on. It's excessively easy. Your readers may like to amuse themselves with its further elaboration.

SHORTFELLOW.

### DEVELOPING DISH FOR AUTOCHROMES.

To the Editors.

Gentlemen,—On October 15 I described in a photographic contemporary a special non-frilling dish which I had designed for the development of Autochrome plates, and gave a diagram of the experimental dish which I had then constructed. At my subsequent demonstration on this plate to the Catford and Forest Hill Photographic Society I used the dish and explained its construction.

I am flattered to find from to-day's issue of the "B.J." that Messrs. Fallowfield have adopted my idea, including the well at the end of the dish to hold the solutions while the plate is being examined; but in case of any misapprehension as to my connection with Messrs. Fallowfield's dish, I think it is only right to explain that my dish, in a greatly improved form, is being placed on the market by Messrs. Houghtons Ltd., under the name of "Campbell's Non-Frilling Developing Dish," and this is the only pattern with which I have anything to do. This improved pattern will be found to render the development of Autochromes a certain and simple operation, in which the frilling of the films becomes impossible.—Yours, etc.,

W. GORDON CAMPBELL.

18, Kinver Road South, Sydenham, S.E.

To the Editors.

Gentlemen,—We thank you for yours, dated 3rd inst., with reference to the letter you have received from Mr. Campbell.

It is quite right that, by arrangement with Mr. Campbell, we are putting on the market in a few days a special dish for developing Autochrome plates on the lines of the dish described by Mr. Campbell recently in one of your contemporaries.

We shall have pleasure in sending you a specimen of this dish with illustration and particulars as soon as we are able to define the prices, etc.—Yours faithfully,

88/89, High Holborn.

To the Editors.

Gentlemen,—With reference to the letter you have received from Mr. Gordon Campbell, and which you were good enough to show me, I am extremely surprised that Mr. Campbell should have imagined either that I had copied his idea with reference to the non-frilling dish,

or that I had made a pattern from the description which appeared in the "Photographic Journal" some two weeks ago without acknowledging where I obtained the idea or obtaining permission for copying that idea. My own dish, which is fully described and illustrated in your JOURNAL, is merely an adaption to the old-fashioned glass-bottomed dish, which I sold in large quantities over twenty years ago, made up from one of these original dishes, and the only improvement is that a small frame, which has an india-rubber bed, is supported on top of the negative, and shields it from the solution. I may also mention that one or two prominent photographers have been using this dish with great success, but I shall not have a full stock for some ten days.—Yours faithfully,

146, Charing Cross Road, W.C.

JONATHAN FALLOWFIELD.

### THE ARTIFICIAL LIGHT EXHIBITION.

To the Editors.

Gentlemen,—On Friday last I had an opportunity of visiting the most interesting exhibition of photographs taken by artificial light.

An exhibition of this description should prove of inestimable value to all enterprising members of the profession, who would do well another year by adding their efforts to the collection on a more generous scale.

I feel myself, like others, remiss on this point. Controlling, as I do, over a dozen branch studios, all using artificial light exclusively a few samples taken by my particular system might be of interest to others, and I am taking the liberty of sending along a few prints showing a description of the work produced by an arrangement of my own construction of several electric arc lamps.

Portraiture by artificial light presents a vast field for experiment, and, from a commercial standpoint, unlimited possibilities naturally present themselves. I feel sure that this exhibition will be keenly interesting to all and become an annual event of importance.—Yours faithfully,

J. H. WOOLFE.

[We will make a note of our correspondent's suggestion. Another exhibition of the same character may well be brought together by general invitation. We did not adopt this course in the present instance as we were doubtful of obtaining a sufficient response. Eps. "B.J."]

### RODINAL DEVELOPER.

To the Editors.

Gentlemen,—Recently we have had brought to our notice several instances of dealers and amateurs failing to obtain a supply of Rodinal.

This would be surprising considering the liberal amount spent on advertising, but that we understand that rumours as to the withdrawal of Rodinal from the market are being passed round.

We would therefore ask you to insert this letter of ours, stating that, as sole agents for the "Agfa" patent developers, we hold a large stock of Rodinal, Metol, Amidol, Glycin, etc., at the disposal of the trade and public.

It is as well to nip such rumours in the bud, although so far no harm has been done, our sales for 1907 (ten months) being far in advance of any previous year (twelve months), and it is certainly not the intention of the manufacturers to withdraw an article that is in such a flourishing condition.—Yours truly,

CHAS. ZIMMERMANN AND CO. (PHOTOGRAPHIC), LTD.

9 and 10, St. Mary-at-Hill, London, E.C.

October 31, 1907.

**FRACTURE OF PLATE GLASS BY LETTERING.**—The painting of black letters by signs on plate-glass windows (writes the "Chemist and Druggist") appears to involve considerable risk of fracture of the glass. The fact is so well known that some insurance companies will not accept the risk. The explanation of the phenomenon is found in the property of a black surface to absorb the sun's rays, whereby unequal expansion is produced, and this, under the influence of a sudden change in temperature, develops a strain which shatters the plate-glass. Such accidents, however, are not confined to black-painted lettering. We have recently heard of a case in which transparent glass tablets, cemented on to the windows being exposed to sunlight, whilst others were out of reach of the sun's rays. The cement used, however, was a black compound, and this, of course, might be expected to act in the same way as the black paint. In every case, on removal of these tablets, the plate-glass was found to be in a cracked condition. It would be interesting to know how far light-coloured paints are free from this drawback, and whether elastic light-coloured cements could be used with advantage.

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

1. Symonds, 39, High Street, Portsmouth. Photograph of H.M.S. "Good Hope"

Edgson, 153, South Parade, Cleckheaton, Yorks. Photograph Snapshot of Dr. Dalry's Funeral, taken in Stonevond Cemetery, Halifax.

MacKie, The Pharmacy, Culter, Aberdeenshire. Photograph of Rob Roy Statue, Peterculter, Aberdeenshire.

10. Crown Street, Aberdeen. Photograph (Combination) of a Placed Group containing the Players, Reserves, Directors, Trainer, and Secretary of the Aberdeen Football Club, Season 1907-8.

19. Commercial Road, Bournemouth. Four Photographs of Roughies from the Undercliff Drive, Bournemouth.

M. J. Keane, 8 Main Street, Arklow, County Wicklow, Ireland. Photograph of the Very Rev. J. Dunphy, Parish Priest of Arklow.

23. High West Street, Dorchester, Dorset. Four Photographs of the Rev. Dr. C. Graham, R.C. Bishop of Plymouth.

W. Thomstone, 2, The Grove, Whitworth Park, Manchester. Photograph of H.M.S. "Lusitania" in the Mersey, September 7, 1907.

S. Wile, 100, Wolverhampton Road, Stafford. Photograph of John Knight, Esq., Major. Photograph of Wm. Johnson, Esq., J.P., Major.

Dean, 14, High Street, Rugby. Photograph of the Reception at Rugby School of H.R.H. Princess Henry of Battenberg, October 26, 1907.

Photograph of the Reception at Benn Buildings, Rugby, of H.R.H. Princess Henry of Battenberg, by the R.U.D.C., October 26, 1907.

Photograph of the Opening of the Children's Ward, Hospital of St. Cross, Rugby, by H.R.H. Princess Henry of Battenberg, October 26, 1907.

Photograph of H.R.H. Princess Henry of Battenberg at the Rectory, Rugby, October 26, 1907.

G.—Your letter will be admissible for publication on your sending your name and address, not necessarily for publication, etc.

KOR.—I shall be glad if you would be good enough to give me information where I can buy a Kromskop, one of Ives' patent.

—B. SHARP.

They are not sold now except by the Scientific Shop, 324, Dearborn Street, Chicago. You can occasionally see one in Mr. Steven's weekly auction lists (King Street, Covent Garden, W.C.), or a small advertisement in our pages would most likely bring you into touch with a vendor.

as. BROWNING.—(1) We admit the justness of your criticism. The table has been withdrawn. That in the forthcoming (1908) "Almanac" will be found in accordance with average practice. (2) The sulphite is quickly destroyed. It is best to keep it separate from the alkali, and to neutralise its solution with potass metabisulphite.

ED. BROMIDES.—Enclosed please find a toned bromide postcard. I should be glad if you could give me any idea how the colour is got.—TONEER.

By the hypo-alum process, as per the formulæ in the "Almanac," 1907, page 988, or by one of the more recent sulphide processes, some articles on which appear in the 1908 "Almanac." TRYING ON GLASS.—Can you give me formula or tell me where I can purchase an ink that will write on glass?—J. E. S.

An etching "ink" is sold as "Sabatier's," by Baird and Tatlock, Cross Street, Hatton Garden, London, W.C.

W. COOPER.—Apply to Erdmann and Schanz, 109, Bedford Hill, Balham, S.W.

DEVELOPER.—Kindly tell me which is the most economical way of buying developer for bromide and gaslight papers—say amidol or metol. I frequently require to develop, say, a dozen or two cabinets, and at other times 100 postcards, and am at a loss for a cheap and easily made-up developer. Will you say if the cartidge form of developer is as cheap to buy as buying the chemicals separately?—A. H. CLARKE.

For such small quantities it will be cheaper to purchase cartidges, but for larger numbers a metol-hydroquinone developer, made up from the chemicals, is the most economical.

—Apply to Houghtons, Ltd.

C. C.—Your procedure cannot be taken exception to, but we should advise you to use the gold platinum toning in separate baths; it is usually more satisfactory than platinum-toning alone.

COPIES OF PAINTINGS.—I have some carbon prints of National Gallery pictures, by Sir E. Landseer and by Turner, and should be glad if you would kindly let me know, in next week's "B.J.," whether they would be copyright, and if I should be justified in reproducing them for sale.—T.

Most certainly the copies will have been registered by the firms making them. Your best course is to ascertain who they are—probably the Autotype Company, Hanfstaengl, or Hollier.

S. H. MEDCALE.—If you owe the man money he has a lien on the apparatus. If you do not, he has no right to retain it, and you can take police court proceedings for its recovery. The man is certainly entitled to a clear week's notice, or full wages in lieu of it. Before taking police court proceedings we should advise you to consult a solicitor, as, from what we can make out from your letter, which is somewhat vague, you made a very loose arrangement at the beginning.

COLOUR PROCESSES.—1. Where can I obtain all materials for the pinateype process? 2. Messrs. Sanger, Shepherd and Co. claim sole right to print from a dyed gelatine relief obtained by the wash-out process. I feel sure I have read of such a method of printing years ago. Can you tell me if there is any foundation for their claim? 3. Can you give me the simplest possible formula for a dry plate emulsion? It need be no more rapid than an ordinary process plate. Simplicity and ease of preparation are the important points.—CHROMOGRAPE.

1. All materials for the pinateype process can be obtained from Fuerst Bros., 17, Philpot Lane, E.C. 2. We know of no process which antedates the Sanger-Shepherd printing process. 3. An easy process for a slow emulsion is made as follows:—

Distilled water .....	20 ozs.
Hard gelatine .....	3½ ozs.
Citric acid .....	1 oz.
Ammonium bromide .....	768 grs.
Potassium iodide .....	20 grs.

Soak the gelatine for an hour, and then add the salts and dissolve by heating to 120 deg. Fahr., then add the following in a thin stream, stirring all the time:—

Silver nitrate .....	1,152 grs.
Distilled water .....	20 ozs.

Add sufficient liq. ammon. fort. 880 to dissolve the precipitate first formed. The temperature of this should not exceed 70 deg. Fahr. Allow the emulsion to stand for quarter of an hour after mixing, then add—

Hard gelatine .....	3½ ozs.
---------------------	---------

which must be previously washed and drained. When this gelatine is dissolved, pour the emulsion out into a flat dish to set and allow to stand twelve hours, and then break up and wash.

SULPHIDE.—The commercial sepia bromide card is produced by the older hypo-alum toning, using a formula such as that on page 988 of the 1907 "Almanac." This method gives a certain purplish bloom, which is not exactly like P.O.P., but is, nevertheless preferred in the trade. The prints are put through an alum bath, then into the hot hypo-alum mixture, which must be used for some time before it attains its full working qualities, or may be "ripened" by soaking untuned P.O.P. clippings in it.

FINISHING IN BLACK AND WHITE.—In working up bromides in black and white, by what means are shadows usually reduced, and, in some cases, completely hidden? I tried various whites, such as Chinese and flake, which were tinged to match the print, but when dry they appear different to colour of the print.—BARNARTT AND COHEN.

It seems clear that you have not rightly matched the colour. The shadows are frequently softened by reducing them with an ink-eraser, or with fine pumice powder or by scratching away with a knife. You might try that method. We should think you would do well to get two or three practical lessons in finishing enlargements from an experienced worker.

AVOIDING YELLOWNESS.—When retouching bromides chemically, as given in the "Almanac" for 1907, page 792—while it entirely

removes the image, yet it leaves the place yellow—how could the yellowness be avoided, and does the print want washing after it had received the above treatment?—M. B.

More ammonia added to the acid copper solution is probably required. We should advise, in preference to the copper solution, the iodine-cyanide reducer, given on page 670 of the 1907 "Almanac."

R. L.—Until you have acquired greater knowledge of the business than you possess at present we should advise you to give up the idea of issuing the printing papers. The dealers have quite enough brands of paper to stock as it is—get the views of your local photographic dealer—and you will find it very difficult to bring a new brand on the market—particularly so as your technical emulsion experience is nil. You will be foolish to take a roseate view of the profits likely to be made under your suggested scheme. If you were in town we could grant you a few minutes, that is if you arranged an appointment beforehand.

CANADA.—Will you kindly tell me (1) the best means of advertising for a situation in Canada or U.S.A.? (2) The name of the publishers of a good book on retouching?—CANADA.

(1) "St. Louis and Canadian Photographer," 3 and 10, Locust Street, St. Louis, Mo. (2) Dawbarn and Ward, Ltd., 6, Farlington Avenue, E.C.

PRESS PHOTOGRAPHY.—(1) Regarding focal plane reflex cameras, which would you prefer to use for press work—a half-plate or 5 x 4; and which size is most popular with the best press photographers? (2) I had to photograph a rapidly moving crowd (waving hats, etc.) with an 8 in. focus anastigmat (stop f/6). Day dull, distance from crowd about 30 feet. What approximate speed of shutter would you suggest? (3) I have two rather valuable albumen prints that have been spoilt by oil getting on them. Can it be removed? One seems almost saturated with it.—H. F.

(1) Half-plate is in the majority among press photographers in large towns; in a wider area we should expect to find 5 x 4 more used; nothing smaller, however. (2) If the figures extend into the immediate foreground a very short exposure will be necessary, 1/75 to 1/100 of a second will not be too short, perhaps not short enough. (3) None that we can recommend. Try benzole, followed by warm dry blotting-paper.

F. W. T.—Address at West Kirby, Cheshire.

STUDIO QUERY.—Would you kindly advise me on the following: I am building a studio facing east. Would ground glass cause too much glare from the sun, or would it be better to have Hartley's rolled plate (white)?—H. A. AYLWARD.

There would not be much difference between the two as regards glare. On the whole, however, we should recommend the white rolled plate, as it will be less trouble to keep clean than ground glass would be. It is also much stronger.

DISPUTED ACCOUNT.—Just recently I gave an order to a carpenter to erect me a studio, portable, and a tenant's fixture, 18 ft. x 9 ft., and he contracted to do this for the sum of £17 complete. Upon the day of starting the job the building inspector for this borough told the builder that as the ground was of a soft nature he would have to put a foundation for it of 18 inches. Now that the building is finished I have received a bill for same with an extra for £4 16s. "for foundations as ordered by the building inspector." I have protested against this, and have told the builder that I am under the impression that he should have known his work and have allowed for this. Not wishing to be hard on the man, I agreed to give him £2 (pointing out that I did not consider myself liable), but this he refuses. I should be glad if you could tell me my position. Nothing was said about paying for any extras, as none were anticipated. I was not consulted as to whether the builder should proceed after the inspector had ordered the foundations. I presume that there would have had to be foundations of some sort included in the contract price.—IGNORAMUS.

It seems to us that you will have to pay the full amount. Unless the foundations, as ordered by the building inspector, were put in you could not have your studio. The builder could not have foreseen what would have been the inspector's requirements when he gave the estimate, and we think his charge for an 18-in. foundation for a building of that size very moderate.

He would have done better, perhaps, had he told you before commenced the work that the foundation would be an extra. Yet it is only fair that the builder should be paid for what he had to be done.

HYPOCO.—We have now tried the preparation, and find that action is no more than that of pure water.

H. BROWN.—The best kind of plate is a "process" of "photo-mechanical," several brands of which are on the market.

A. K.—You had better apply to Meister Lucius and Brünig Hoeschst & M., Germany. They will advise you re dyes, and will be able to supply what you want if it is obtainable.

ELWES.—1. Of course he can exhibit what he has paid for, but cannot copy. 2. Legally, he cannot.

DE JURE.—You may make and register a copy of the engraving so may anybody who has access to it. You cannot restrict them, or they you, from publishing copies—that is, if the latter are made from the original.

PUZZLED.—Not powerful enough.

W. T.—Condenser is not large enough for whole plates; it should be 11 in. clear diameter. This is one cause of the trouble, most probably the colour rings are chiefly caused by the use of an unsuitable objective. One of too small a diameter will give such an effect. The green colour of the condenser is not likely to have anything to do with it. Most cheap condensers are distinctly green, and only the best and dearest quality are quite clear.

B.—1, 2, 3. Apply to the Director of Education, City and Guilds London Institute, Exhibition Road, S.W., or to the Photographic School, Regent Street Polytechnic London, W., particulars of the City and Guilds examination. 4 and 5. There are no special examinations. 6. The City and Guilds publish a list of books. 7. They are not distinct. Art matters, however, are not included in the examination syllabus, and never likely to be.

A. E. G.—Acetylene is rather bulky, but apply to Thorn's Huddle, Victoria Street, S.W. The Ideal lamp, of Houghton Limited, would probably meet your requirements better.

RATING SHOP.—I should be pleased if you will inform me, through the "B.J.," whether a tenant, taking a shop for the sole purpose of a showcase, is liable to pay rates, no business whatever to be done at the said premises?—B. S. J.

As the premises are occupied and used for business purposes the tenant has to pay the rates. You say business is not done on the premises; but is not using the place for advertising occupying it and for business purposes?

F. MILLS.—1. We do not very well see how you can make use of the circumstance on your stationery. It seems that Her Royal Highness condescended, at the request of the vicar, to sit for her portrait, and you took it accordingly. It seems that you did it for the vicar and not for you. If you wish to use Royal Arms, and that is possibly your idea, you will have to obtain the Royal Warrant, and that you are not at all likely to do on the ground that H.R.H. permitted her portrait to be taken by you. 2. Surely you have overlooked our announcement last week on p. 822.

A. I. N. (Ramsgate).—See page 799 of our issue of October 1907, reply to "T. Corn."

C. H. B.—You are certainly entitled to a week's wages if your product was no more irregular than you state.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Control in Developing Autochromes.—MM. Lumière have issued directions for dealing with the over and under exposure of Autochrome plates and with variations in the temperature of the developer. Their recommendations are given on page 863.

Autochromes from Autochromes.—Some further specimens have been placed on exhibition at the house of the "B.J.," where they can be seen during the period of the present exhibition of portraiture by artificial light. (P. 858.)

Varnishing Autochromes.—A point in fully protecting the Autochrome film is referred to on page 859.

Carbon Enlargements Direct via Bromide Paper.—We publish a description of the new "Carbograph" paper, and an article on its manipulation by Mr. Welborne Piper, one of the first workers in this new process. (P. 860.)

Some facts and fallacies of stand development are the subject of recent communication from Messrs. Wratten and Wainwright. (P. 864.)

Mr. Robert Barr, the novelist, has patented a changing box. A folding reflex camera and a process of colour-photography are among their patents of the week. (P. 868.)

A suggestion of a novelty in portraiture for the professional's window is made on page 858.

The Germans have claimed priority in the origination of the oil process. (P. 859.)

Recent progress in the telegraphic transmission of photographs is recorded on page 866.

The common-sense view (a man's) of Christmas cards. (P. 872.)

Dr. Mees is announced to lecture on screen-plate colour processes at the Society of Arts after Christmas. (P. 872.) On November 25 Mr. Conrad Beck commences a course of lectures on the theory of the microscope. (P. 875.)

Baron von Hübl's measurements of open and enclosed arc lamps are the subject of a further article on page 865.

## EX CATHEDRA.

**"The British Journal Almanac."** The work of the Editor and the no less titanic labours of the advertisement manager having come to an end, and the last whirr of the printing machines having ceased some time in the early hours of a recent November morning, the masses of printed matter which compose the "B.J. Almanac" are at the present moment passing through the last metamorphosis preparatory to distribution, to the number of 25,000 copies, throughout pretty nearly every country of the globe. Every photographer in the United Kingdom can, if he so desires, purchase it at his dealer's on Monday, December 2. The date of December 1, which is the regular nominal date of publication, was, we regret to say, announced in our pages without regard to the fact that it falls on Sunday. We must plead—as excuse for the offence which the intimation has caused in strict Sabbatarian circles—our carelessness (or, happy thought, that of our publishers) in overlooking the fact. Photographers, too, we are afraid, will blame us for placing a week-end between them and the anticipated of months; but, unfortunately, our publishers, mere commercial men, are as adamant in refusing to accept the responsibility of delivering the "Almanac" through the country on a Saturday. Still, nothing but a miracle or a railway strike will prevent them from placing the edition in the hands of the retailers on Monday, December 2.

**The 1908 Almanac.** As for the contents, form, and size of the corpulent friend of whose society we have had quite as much as we care about for the past three months, there have been some slight disturbances of his anatomy, and one or two vital organs have been displaced. The net result of these adjustments should be approved by every reader of the "Almanac." It is that:—

The indexes to text and advertisements respectively are placed together at the end of the volume.

The directory of the addresses, postal and telegraphic, and of the telephone numbers of the photographic is also placed next to these two indexes, for the sake of the hurried reader, who has in the past laid his sins of explosive language at the doors of our innocent selves, on account of the alleged difficulty of quickly turning to a given item of information. The charge can no longer be brought, and we hope the arrangement of the text-index will further facilitate reference to the great mass of information in the "Almanac." The index to advertisements is, of course, as comprehensive as befits the importance of its subject-matter.

**Colour Prints on Paper.** The process of the future, in reproducing on paper the colour results now so easily obtainable as transparencies—what is it to be? There is no doubt that a good deal of work is quietly being done to provide a method by which the one-plate negative or

positive may be transferred to paper without the labour involved in the three-print method of superimposition. The bleach-out process, even if it can be further perfected, is not without its limitations, although, in the case of screen-plates of linear formation, it is easily amenable to the production of the full range of colours in the positive. It is probable, however, that the converse of the bleach-out process may prove a more fertile field of research, that is to say that it may prove easier to devise a working process in which coloured compounds are formed on exposure to light than to apply the bleach-out method. The transformation of leuco compounds into colouring matters by the action of light is well known, though whether a mixture of such leuco compounds can be prepared of the necessary absorptive properties to print in colours at one operation, requires to be discovered. We may refer those interested to the so-called pinachrome process, described in our issue of October 14, 1904, and briefly referred to in the Almanac of 1906, p. 865.

\* \* \*

#### Autochrome as Professional Advertisement.

From newspaper extracts which reach us from many different parts of the country, we see that the Autochrome plates continue to render good service to professional photographers on the alert to their possibilities from an advertising point of view. The display of an Autochrome portrait of a sitter who is well known locally has given good cause for a paragraph in the newspapers of the district. As an example of the type of paragraph, we quote one actual example here, suppressing only the name and address of the firm:—"During the past few days there has been on exhibition in the window of Messrs. J— and Son, photographers, P—, a portrait of a young lady taken by the Autochrome process of photography. Although many experiments have been made for several years past in connection with colour photography, it is only recently that any perfection has been reached, and, so far, the Autochrome process, discovered by M. Lumière, has been most prominently before the public. The portrait referred to was taken by Mr. — in the studio of his firm, and it is an exquisite work of art. The colouring of the face and costume of the subject, as well as the hanging draperies in the background, are perfect in every detail. Being taken in a studio, the work presented many difficulties in connection with the exposure of the plates, and it is no discredit to the Messrs. S— that the first few attempts proved fruitless. So far as is known, this is the first portrait in colour successfully taken in a studio in the north."

#### Shadow Portraits.

The illustrative pages of our always sprightly contemporary, the "Sketch," have in the past often afforded us the opportunity to point a lesson to photographic portraitists, for the "Sketch," even through its limited medium of half-tone printing, constantly giving its readers novel effects for the production of which the camera is solely responsible. In the series of portraits—of ladies of the stage, let it be said—to which we are now referring, excellent use is made of an artificial source of light to give one and the same print direct portrait, and a secondary silhouette representation of the subject. The latter is, of course, the shadow cast on the background, though we conceive that it may be liable to improvement at the hands of the retoucher should it not conform to other photographic standards of the lady's beauty of profile. Our object, however, is not to quibble over what is legitimate in the beautification of the feminine form, but to point out to our professional readers what an exceedingly good novelty photograph is here presented, and how easily they might make use of the "Sketch's" inventive genius to produce a few results which would certainly create comment on their exhibition in the show-case or window, even if they did not attract orders.

\* \* \*

#### Autochromes from Autochromes.

A correspondent has very kindly sent us some interesting specimens of contact copies of Autochromes printed by magnesium, some being prints from positives and some from negatives. As Mr. Welborne Piper pointed out in his article in our Colour Supplement of November 1, magnesium light is too yellow for the purpose, and thus a print from a positive shows a slight yellow veil, while that from a negative shows a blue veil. These effects are very distinctly apparent in these new examples, as are also the two forms of degradation that, as Dr. Mees pointed out, must exist when making positives from positives and from negatives. These effects are especially well shown in the case of a flower study. The copy from the positive shows the yellow veil and the black degradation, while that from the negative shows the blue veil and the peculiar effect of transparency caused by dilution with white. These examples have been put in our exhibition room for inspection by visitors to the exhibition of portraiture by artificial light, and they, together with the set of copies by Mr. Welborne Piper, form a very complete and interesting series. Contact copies by magnesium, by incandescent gas and by daylight, are thus available for comparison with copies produced in the camera.

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

The forty-seventh annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 2. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

Among other alterations and improvements which have been made in the forthcoming volume, the publishers beg to announce that:—

All three indexes (text, advertisement, and trade addresses) will be found AT THE END OF THE VOLUME.

The size of the volume has been appreciably reduced, without sacrificing the value and scope of the contents.

The editorial article will deal very completely with the important subject of—

SCREEN-PLATE THREE-COLOUR PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The 1908 ALMANAC will contain as frontispiece a carbon print by the Autotype Co., dry-mounted by the Adhesive Dry Mounting Co., Ltd. Amongst other attractive insets will be found a specimen of three-colour printing by the Sanger-Shepherd Colour Printing Co. and examples of the three-colour work of Hood and Co., Ltd., Middlesbrough.

Our publishers desire us again to caution our readers against postponing the booking of their copies of the ALMANAC.

#### PUBLISHERS' NOTICE.

The publishers beg to inform agents that it will be advisable to place their orders for copies immediately, as a large proportion of the issue is already booked, and a second edition will not be printed.

**Oil  
process for  
many.**

It appears that the Germans would wrest from Mr. G. E. H. Rawlins the honour which is rightly his of having applied the principle of collotype to the making by hand of photographic prints. Trust the Teutonic writer to disappear somewhere in the obscurities of his country's literature in anticipation of the modern process. In the case of oil print it was Emanuel Mariot, so we learn from Professor A. Albert in "Eder's Jahrbuch," who in 1866 printed a photographic impression on copper-plate paper, and pigmented by the subsequent application of a greasy ink by means of a velvet roller. Each print was mounted and varnished. We do not question the historical accuracy of the description, but the main fact is that the late Herr Mariot was as silent in 1866 as he is now on the essential nature of the oil-process; namely, its facility, if we may so express it, of not being inked: in other words, that the process allows the pigment to be deposited or not, as the operator thinks best. This Mr. Rawlins may justly claim to have been the first to recognise and to have applied in his editorial ends.

\* \* \*

**Note on  
varnishing  
chromes.**

As already stated, we have found celluloid dissolved in amyl acetate to be by far the best varnish to use, but we have met with one or two cases in which the varnished film had a tendency to rise and curl up at the edges. This may be attributed to the nature of the varnish, for in rare circumstances it would no doubt have occurred on any other kind. To prevent it we have adopted a process that we have often employed before in the case of many stripped gelatine films laid down on glass, which sometimes show a similar tendency to rise at the edges. The film is laid on the plate about one-eighth of an inch from the edge, and a cut is made through the film with a knife, moving the rule a small flat chisel is then run along the edge so as to pare off all loose film. This is done on all sides of the plate, which is then varnished right over the edges of the glass. A perfect seal is thus obtained at the edges, and the film cannot rise or "frill" any further without breaking through the film of celluloid, which is too tough to permit any such rupture.

\* \* \*

**Speaight  
the  
Marble Arch.**

We are interested in learning from incidental letters in the London press that all goes well with the scheme of Mr. Speaight for isolating the Marble Arch from Hyde Park and virtually moving it into a position which will relieve the congestion of traffic which occurs at this point of West End London. Mr. Speaight, in a letter to "The Telegraph," allays the fears of those who have feared that the isolation of the Arch would detract from its position as a London landmark. He instances the recent improvements in the neighbourhood of the Wellington Arch by which a roadway has just been formed round that arch. Mr. Speaight may congratulate himself that he has gained a measurable distance of seeing the realisation of his plans for the improvement of one of London's busiest highways. Even if he has to confess himself unequal to the task of moving Big Ben to somewhere east of Wellington Street! (See our advertisement pages.)

\* \* \*

**Fading  
mounts.**

Of recent years there has been a great demand for what are, very illogically, called "Art" mounts and mounting papers. Why they are called so we do not know, unless it is because they are "art" tints. But then we have never been able to

understand what an "Art tint" is, or how it is specially distinguished from any other tint. There is, however, one very disconcerting feature of the popular art mount, and that is the readiness with which it fades if exposed to strong light. All the tints are not equally sensitive, but the dark greens and olives seem to be exceptionally fugitive in sunlight, and these, unfortunately, are among the most popular colours. In some cases a few days in sunlight is sufficient to bleach the green into a dirty light brown, therefore it is obviously wise to test all mounts before use. Of late years we have frequently heard comments on the hideous tone of the mount in the case of particular exhibition pictures. Sometimes the colour has been so bad that it became impossible to believe that it had ever been deliberately selected. Probably in most instances it was simply a case of fading, and the exhibitor did not deserve the charge of bad taste that was hurled at him. We may, however, very fairly accuse an exhibitor of carelessness if he mounts a print in a permanent process, such as carbon, gum, or oil, on a mount that will not retain its colour. Remounting a print is no easy task, therefore it is quite an important matter to use a mount that will last.

## MATT CARBON.

### II.

A somewhat less flaccid feel is necessary with prints intended for opal instead of flexible support before squeegeeing, otherwise the edge of tissue may buckle in places. The rubber of the flat pattern squeegee will soon get notched and cut upon the edges of the plates; it is therefore customary to grind the edges of the plates. With regard to the squeegee, many printers suddenly find increasing numbers of blisters from an unknown cause. When this occurs the squeegee should be looked to, and if the rubber is soft and yielding or loose in the wooden handle, a new one should be purchased, or a new blade inserted, as may be done in a new pattern of squeegee just placed on the market.

The plates as they receive the prints should be laid face down upon one another with blotting paper between, placing the first one on a piece of flat glass. A fairly heavy weight should be kept upon them, and the pile limited to fifteen. Should there be about fifty prints to transfer, the first pile will then be ready for developing, and should be placed in rack with an inch or so of space between each plate. It is plunged into the developing water previously adjusted by thermometer to 105 deg. Fahr., moving up and down again to remove airbells.

The tissue will soon "bleed," and the backing should be stripped from the plates as soon as possible. The prints may then be left to develop themselves, but it is far better to remove each one singly from the racks and lave with water to remove the dissolved pigment.

The prints will probably not develop at the same rate, and those ready first should be at once removed to a tank of clean water. We lay stress on this, since leaving to soak in the hot water usually means prints covered with minute blisters, looking like tiny white spots in the print, and resembling air bubbles more than blisters. For this reason over-printed images can seldom be saved on opal by using hotter water or leaving to soak. We cannot understand why the blisters should be so minute; ordinary support does allow a lot of boiling, but when prints upon it do blister the latter are always large. The tissue seems to adhere rather more firmly to the flexible support, for it is almost impossible to avoid frilling on opal when the

safe-edge is on the film side of the negative, and a very heavy stream of water will often wash up a heavy shadow. The zinc racks should not be placed in alum solution, which may either be put in a very large shallow dish, in which the plates can lie, or into a wooden tank with wooden grooves cut into the sides, which will take a large number of plates in a small space. The plates need only be five minutes in alum, and the subsequent washing need take no longer if two changes can be given in that time. This means a tremendous saving of time, and is a very great convenience for workers, for the batch can be started and finished straight away without long waits for alum and for subsequent washing necessary when paper supports are used. Moreover, it is well known that the sooner a print can be developed and finished the more certain and better the result, as there is less chance of dust and dirt adhering to the gelatine.

After squeezeing the final support on to the carbon

film, the whole is placed in the racks and left to dry. attempt should be made to strip from the plate before paper is absolutely dry, or very bad marks will be the result.

Before concluding we must point out the greatest advantage that opal temporary support used in racks over the other variety, and that is the entire freedom of the prints from abrasions. It is well known how tender gelatine film is frequently scrubbed by the edges of other prints developing or washing at the same time. papers have such a tendency to cling together that the very greatest care can avoid much loss from this cause.

In point of view of the superiority of opal, we think professional printers will bear us out when we say that it is often difficult to get clean vignettéd carbons when on flexible support, the result being nearly always "bit" and scratched with light streaks on the lights, meaning either total waste or much aerograph work. This is entirely obviated when using opal plates.

## CARBON ENLARGEMENTS DIRECT BY ARTIFICIAL LIGHT ON "CARBOGRAPH" PAPER.

FOR some time past short announcements have appeared as to the introduction of a new type of printing paper which should combine in itself the quality of permanence of carbon with the facility of production by artificial light, which that material possesses. This new printing medium has at length appeared in the shape of the so-called "Carbograph" tissue of the Rotary Photographic Co., by whom it is issued at prices which are almost exactly double those charged for ordinary bromide paper. That the new material is obviously a quite new departure in printing methods is obvious from a perusal of the articles which appear in this issue. It will be found that in taking the first opportunity of laying particulars of the new method before our readers we have not allowed ourselves a licence of space in excess of the interest with which this innovation in pigment printing is certain to be regarded. With "Carbograph" at his disposal the photographer spreads a sheet of paper on his enlarging easel, exposes just as he would a bromide paper, and forthwith produces on any desired surface a carbon print of rich characteristic quality. When we state this—and the fact can be confirmed by any photographer in half an hour—we have shown, we believe, that the new paper can come before the photographic public with a reasonable assurance of being investigated with interest not only by the worker whose aim is the exhibition print, but by the large purchasing class whose particular care is the commercial possibilities of their technical methods.

### The Principle of "Carbograph."

The essential principle of "Carbograph" is not at all complex. The paper carries a bromide emulsion, with which is incorporated a pigment which at present may be red chalk, light green, or warm or cold sepia. On exposure to light and on development an image of metallic silver is formed, just as in ordinary bromide printing. The next step constitutes the new

part of the process. Instead of passing to the fixing-bath, the print is immersed in a bath of bichromate. Here the silver image plays the part of light; it reduces the bichromate, the reduced products tan the gelatine of the emulsion to an extent proportionate to the amount of silver present—thus, to say, the silver image is supplemented by one in insoluble gelatine. The next step is to develop this "carbon" in carbon fashion, and to obtain the print possessing all the permanence and beauty associated with the carbon process.

The silver image, although the active agent in the process, is not itself affected, but is left in the final print. It can be removed if desired, or advantage can be taken of its presence to modify the character of the final "Carbograph."

### The Process at a Glance.

Thus the essential operations in the making of a carbon enlargement by the "Carbograph" tissue are as follows:—

- Exposure of the bromide paper.
- Development as for bromide paper, five to seven minutes.
- Clearing and rinsing, five minutes in all.
- Sensitising in bichromate, three minutes.
- Rinsing, two minutes.
- Transfer to final support, ten minutes.
- Development in hot water, about five minutes.
- Fixing in hypo and washing, about half an hour.

It will thus be seen that within a little over one hour, putting the negative in the enlarging lantern a finished carbon enlargement may be hung up to dry, and that during the greater part of this time the prints need no personal supervision. The precise manipulation required in the process will be further gathered from the following notes by Mr. C. Welborne Piper, one of the first independent workers to take up the new method. We supplement Mr. Piper's article with the essential portions of the official instructions for the use of the paper.

### "REMARKS ON 'CARBOGRAPH' PRINTING," BY C. WELBORNE PIPER

No one can complain in these days that photography is standing still and making no progress, for new and important processes so rapidly follow one another that we can hardly assimilate the principles of one before the next makes its appearance. The very latest is the "Carbograph" process of the Rotary Company, which, from a few days' practical experience,

I can safely describe as a process of the utmost importance and utility. The practical character of the process is proved by the fact that I succeeded in producing satisfactory results from the very first of my experiments. I found it perfectly easy to produce a carbon enlargement direct from the original negative within one hour from the start, using an incandescent

gas enlarging lantern. If this is compared with the ordinary process, involving the production first of a positive, then of an enlarged negative, and necessitating contact printing by daylight, the advantages of the "Carbograph" method are evidently enormous. Besides all this, the result is an image amenable to a certain degree of intensification or reduction, and even to a slight modification of colour.

This new paper is coated with a combination of pigmented gelatine and silver bromide, and the effect of the initial exposure is, of course, confined to the silver bromide. The exposed image is developed with ferrous oxalate or iron citrate, and after clearing and a brief wash it is "sensitised" with a solution of potassium bichromate and alum. The reactions at this stage are evidently akin to those that take place in the "Ozobrome" and the "Bromoil" processes. Though in the "Carbograph" process the silver image is not bleached, yet the gelatine in the immediate neighbourhood of the silver is tanned or hardened, the result being that from this sensitising operation the print can be treated exactly as an exposed sensitised carbon tissue—that is to say, it can be transferred to a suitable support and be developed with hot water in the usual fashion. The hot water then dissolves the untanned gelatine, carrying away with it the pigment, and also the unexposed silver bromide in the highlights. An ordinary hypo-fixing bath removes all traces of unaltered silver bromide that may adhere to or be left in the print, and the result is an image in pigment and metallic silver.

#### Control Methods.

It is the presence of the silver in this resulting image that gives us the control over density and colour that we do not possess in the ordinary carbon process. The colour is deepened by the silver, and we can brighten or lighten it by removing the silver, or further darken it by carrying out an intensifying process upon the silver. The effect varies somewhat with the colour of the pigment, but in all cases reduction materially reduces contrast. Two of the colours in the papers I have tested were "photo-brown" and "light green." The photo-brown plus silver is a strong deep brown, but minus the silver it is more transparent and a very rich red-brown. The "light green" plus silver is a quiet, deep colour. Minus the silver, the tint is much lighter, and the result tends to flatness, so that varying degrees of reduction enable one to control the degree of contrast. The presence of silver in the image is thus a most valuable feature, while it cannot in any way detract from the permanency of the result.

#### Some Guide to Exposure.

As regards exposure, the Rotary Company state that the "photo-brown" and "red chalk" tissues require ten times as

much exposure as ordinary rotograph bromide paper. The "light green" requires seven times and the "warm sepia" five times the exposure for bromide. These ratios I found to be quite reliable, and it is only a matter of two or three minutes to make a series of trial exposures on a slip of bromide and so determine the exact exposure for "Carbograph." Enlarging from quarter to whole plate with incandescent gas, and using an eight-inch objective with one-inch aperture, the correct exposure proved to be about one and a quarter minutes on "warm sepia" tissue with a thin negative. A rather "plucky" negative required eight minutes with "photo-brown" and six with "light green." The former result was just right after complete removal of the silver, but the latter was too thin and flat in the same circumstances. With the silver left in it had just about the right degree of density. These strike me as good illustrations of the short exposures required with a feeble light, such as incandescent gas, and of the control possible over the final result.

From my experience, it appears that the process is quite easy, provided exposure is correct, and this condition also is quite readily ensured. As regards the quality of the results, that is everything that could be wished. If the silver is removed the result is identical with that produced by the ordinary carbon process, and therefore just as good or as bad as a carbon print may be. With the silver left in the effect is only that of a modified and more opaque pigment, and it could be matched by selecting a suitable ordinary carbon tissue.

Curiously enough, though the tissue appears black in the yellow light employed in the first stages, yet the image is very clearly visible on development. With the lighter shades of pigment, all details are visible, hence to a certain extent the progress of development can be judged by observation. I have not yet had time to test the effect of varying the time of development, and have hitherto developed for a fixed period of five minutes. Probably, however, it will be found advisable to vary the time according to the quality of the negative. The process is of such a nature that many slight modifications are possible, and perhaps some of them may prove to be useful in the case of exceptional negatives.

A warning is necessary with regard to the use of stale sensitiser. If too much exhausted, the effect is that of bad under-exposure, and the whole image may wash out in the hot water. If kept filtered, the sensitiser can be used several times, but it must not be overworked.

I found it best to leave the silver in the image until the result was dry, as I could then better judge whether reduction was necessary. If reduction is known to be necessary the hypo and ferricyanide reducing bath can be used in place of the plain hypo bath, and thus the time can be somewhat shortened.

C. WELBORNE PIPER.

#### INSTRUCTIONS IN THE "CARBOGRAPH" PROCESS.

The following are taken, with some slight revision, from an advance proof of the official instructions for the use of "Carbograph" paper issued by the Rotary Company.

The average speed of the "Carbograph" tissue is equivalent to medium speed bromide paper, and it is therefore absolutely essential that packets are only opened and the tissue handled in a safe orange-yellow lighted room.

#### Exposure.

The tissue is as equally suitable for contact printing as enlarging, but care must be taken that negatives selected for this process are always safe-edged to prevent the pigment washing up during development of the carbon print.

It will be found that lighter colours of the "Carbograph" require somewhat less exposure than the deeper one. The test pieces of Rotograph bromide paper in the packets are intended to

be used for trial exposures. The following numbers give the times of exposure compared with that for Rotograph bromide paper:—

Engraving black .....	9 times	Light green .....	7 times
Photo-brown .....	10 "	Warm sepia .....	5 "
Red chalk .....	10 "	Cold sepia .....	8 "

That is to say, if the bromide test slip requires four seconds, forty seconds must be given on the red-chalk "Carbograph."

The most important matter regarding exposure is not to under-time; over-exposure, unless excessive, can generally be easily corrected during the carbon development.

#### Development of the Bromide.

The exposed tissue is immersed without a preliminary soaking in water, in either a ferrous oxalate or iron citrate developer; other developers, owing to their greater or less tanning action,

cannot be advised for "Carbograph." A good ferrous oxalate developer is as follows:—

I. Potass oxalate .....	300 gms.	6½ ozs.
Distilled water (hot) to...	1,000 ccs.	20 ozs.
II. Ferrous sulphate.....	80 gms.	1½ ozs.
Citric acid .....	5 gms.	50 grs.
Distilled water .....	250 ccs.	5 ozs.

Immediately before use add one part of No. II. to five of No. I., and add to the mixture five drops of a ten per cent. solution of potassium bromide, i.e., 24 minims per fluid ounce.

For those, however, who wish to use the iron developer together with the least amount of trouble, and yet obtain results exactly as given by the ferrous oxalate developer, the powder iron citrate developer is strongly recommended by the Rotary Company. This developer keeps indefinitely in powder form, and as long as the precaution is taken of using distilled or boiled water in making it up in solution, and filling bottle to neck, it will be found to keep and work well even weeks after having been prepared. The addition to the solution of a few drops of potassium bromide is advisable.

With correct exposure development will be complete in from five to seven minutes—that is, the deposition of the metallic silver can be seen generally quite distinctly in the shadow and half-tone portions towards the end of time, and especially in the lighter colour tissues. It is, however, advisable always to adopt a constant time for the development, and also uniform temperature (50 to 60 degrees F.) as far as possible to ensure a full amount of metallic silver being deposited in the pigmented film.

#### Clearing.

Development being completed, the tissue should be immersed without washing for one minute in a one per cent. solution of glacial acetic acid.

Glacial acetic acid.....	10 ccs.	1½ drams.
Water .....	1,000 ccs.	20 ozs.

This bath is used to prevent the precipitation of basic iron salts in the film, which might otherwise cause iron stains. After this acid bath the print is well rinsed in three or four changes of water, and then transferred to the sensitising solution as under.

#### Sensitising.

To proceed with the production of the carbon print a bichromate bath is necessary as follows:—

Potassium bichromate.....	40 gms.	2 ozs.
Water .....	1,000 ccs.	50 ozs.
Potash alum (10 per cent sol.)...	20 ccs.	1 oz.

The sensitiser may be used repeatedly if care is taken to always filter through a plug of cotton wool or filter-paper before re-use. It is also advisable to store the sensitiser in a deep amber bottle to prevent its deterioration by exposure to light.

The "Carbograph" print is immersed for three minutes in the above sensitiser, the dish being gently rocked all the time. As care should be taken to prevent air-bells forming on the surface, it is a good practice to gently wipe the surface of the film as soon as it is placed in the sensitiser by passing a flat camel-hair brush (kept for this purpose) across from end to end in each direction.

The temperature of the sensitiser should also be carefully observed; it should not be too warm, and if necessary even cooled by ice in summer or humid weather. A good method to ensure uniformity under ordinary conditions is to make up sensitiser before proceeding with an evening's work, then to place the measure containing the sensitiser in a vessel containing freshly drawn cold water, and to leave it there until required for immediate use; by so doing it is easy to rely on its being at the right temperature.

It is also advisable not to touch the tissue with fingers while in this bath.

The above are, of course, only the precautions observed by the careful worker when working the ordinary carbon tissues.

After treatment with this bath the tissue is immersed in clean cold water for three minutes, or, better, rinsed in three or four changes of water before transferring to mounting paper.

#### Transferring the "Carbograph" to the Mounting Paper.

In order to avoid loss of fine detail in the carbon print, it is essential to squeeze the tissue to a piece of well-soaked transfer paper, and to leave it from ten to fifteen minutes between sheets of blotting-paper under light pressure before development—just as in ordinary carbon work.

#### The Carbon "Development."

Development, which can be done in full artificial light or weak daylight, is proceeded with in the usual way, in hot water. The temperature at first should not exceed 100 to 105 degrees F. When the print on its support has been immersed for about a minute the pigment should show a tendency to ooze out at the edges. This may be assisted by passing the tip of the finger along the safe edge portion of the print to start the action. One corner is then lifted, and the whole of the original support gently pulled away. Generally not more than a minute should be allowed before stripping, otherwise air-bubbles may form in the film.

Development is preferably effected in a fairly deep dish, and a piece of glass or opal may be used for a support, although this is not really essential. Further, unless the print is much over-exposed it is advisable not to pour a direct stream of water over the surface, as is so often done for ordinary carbon, for the reason that under normal conditions it will be found that the pigment is much more soluble, and too strong a stream of hot water is liable to make the resultant print somewhat grainy.

If exposure has been somewhat long, clear high-lights can be obtained by gently passing a saturated pad of cotton wool over these places. It will also be noticed that the safe-edged portions of prints retain a certain amount of insoluble pigment, but this also can be readily removed by passing cotton wool over the edges in similar manner.

#### Fixing.

When development is completed it will be noticed the prints have a milky appearance, due to the presence of the unaffected silver bromide. This is now removed by immersing print in a twenty per cent. plain hypo solution as under:—

Hypo .....	200 gms.	4 ozs.
Water .....	1,000 ccs.	20 ozs.

As soon as fixation commences the print will be seen to gain enormously in brilliancy and depth of colour. When the print is fully fixed (that is, in ten to fifteen minutes), it should be well washed in cold water to remove the hypo, and afterwards hardened in a one per cent. solution of alum to prevent accidental damage to the film. It is then well rinsed and hung up to dry.

The print thus obtained still contains the metallic silver image, but is, of course, absolutely permanent even if this is left in. The worker can, however, if he so desires, remove all traces of silver leaving only the carbon image. To do this the following reducing bath is used in place of the hypo fixing-bath given above is used.

I. Hypo .....	100 gms.	2 ozs.
Water .....	1,000 ccs.	20 ozs.
II. Potass ferricyanide...	100 gms.	2 ozs.
Water .....	1,000 ccs.	20 ozs.

For use take two parts of No. I. and add one part of No. II. The print should be subsequently well washed till all yellowness has disappeared.

In some cases leaving the metallic silver in the print may be considered a detriment, as it has a tendency to darken the tone a little, but frequently it will be found a really valuable aid, especially where the negative used has a tendency to harshness; also, it is quite possible, if the silver image is left in, to intensify the print afterwards by treatment with any intensifier as adopted for bromide work.

### Alternative Method of Working.

If a large number of prints are required the following method may be substituted so as to divide the process into two distinct parts.

After developing and clearing the bromide image, the "Carbograph" is sensitised in the bichromate solution as usual, only it is advisable in this case to use only a half quantity of the added ten per cent. solution of potash alum to the sensitiser, which would read 10 ccs., or half an ounce, instead of that given in the formula. After sensitising and rinsing the print should be fixed and washed, in accordance with the instructions already given, and then allowed to dry.

The transfer of the tissue to its support, and its subsequent hot-water development, can then be carried out at any later date within the limits generally allowed for ordinary sensitised carbon tissues (five to seven days) so long as it is properly stored meanwhile.

Prints which are prepared by this method are much less liable to damage in handling whilst wet than those finished without intermediate drying; but, of course, this method increases the length of time necessary for producing results, and so annuls some of the advantages of the "Carbograph" process.

### Safe-edging.

In "Carbograph" enlarging it is not necessary to safe-edge the negative. Instead, a piece of thin cardboard (as used in stiffening large packets of bromide paper) is taken and the centre portion cut out so as to form a frame half an inch in width, and of outside side corresponding to the piece of tissue. This can then be pinned on the enlarging easel over the tissue, care being taken that both edges coincide, and will effectively safe-edge the tissue and ensure its being kept during exposure.

In judging development of the carbon print it is advisable to stop a little earlier than would be considered correct for

ordinary Rotary carbon tissues, as allowance should be made for the unaltered bromide of silver suspended in the film, which will afterwards be removed in fixing.

Handle the tissue as little as possible during development, etc. The tissue being coated on a good stout support, it is really only necessary to handle it at edges with finger-tips.

### Soaking Transfer Paper.

The thicker transfer papers always require more preliminary soaking than thinner ones, and it is a good practice to place the necessary number of supports for a batch of carbon prints in soak previous to making exposures, so as to ensure their being in proper condition when required later on.

### Correct Position Enlargements.

To obviate reversal of image in enlarging, place the glass side of the negative nearest to lens, and not film side, as is customary in ordinary enlarging.

### The Silver Reducer.

If the ferricyanide reducer is to be used on Carbograph for obtaining a pure carbon image, care should be taken to see all traces of the sensitiser are washed out after hot water development, otherwise traces of potash alum left in suspension may cause blue stains directly the Carbograph print is immersed in the reducer.

In preparing the sensitiser it is always advisable when the potassium is all dissolved (hot water should be used for this) to pass the solution through cotton wool or filter paper to remove all suspended matter before pouring into the stock bottle; also as the bichromate should be kept from exposure to strong light, the sensitiser should be stored in a deeply-tinted bottle, or the ordinary bottle wrapped in brown paper.

The double transfer process can, of course, be used if desired, as for ordinary carbon, but in enlarging this is not necessary, as correct position prints are obtained by reversing the negative in the lantern as previously mentioned.

### Choosing the Squeegee.

It is advisable to always use a good quality flat squeegee—one having a strip of easily flexible rubber—as it is important that the tissues should not be too roughly treated during this process, and many squeegees of inferior quality contain only rubber resembling ink eraser more than anything else.

**AUSTRALIAN DUTY ON PHOTOGRAPHIC MATERIALS.**—The Acting Prime Minister (according to the correspondent of the "Chemist and Druggist") stated, in reply to a question in the House of Representatives on September 26, that a duty at the rate of 15 per cent. is being charged, and paid under protest, on photographic dry plates and negatives (whether of foreign or British manufacture), notwithstanding that under the new tariff the duty is only 5 per cent. on foreign imports and British imports are free. He explained that the deposit of the higher rate is necessary, because at present that is the only duty sanctioned by law. Should the proposed tariff not pass into law, the old rates would necessarily be reverted to. In the event of the new tariff being enacted, all the duties now collected would be refunded, because there would be no legal authority to retain them.

**MODIFICATIONS OF THE AUTOCHROME DEVELOPER.**—As the result of a series of experiments made by MM. A. and L. Lumière and Seyewetz it has been found that the formula for the first development of Autochrome plates is still the best which the makers can recommend, but may be considerably modified in certain respects

if the temperature departs at all from that of 60 deg. F. or if errors of exposure are to be compensated for. The colder the developer, the longer should be the time of development, and vice versa: at 50 deg. the time should be four minutes, at 70 deg. two minutes, and at 80 deg. one and a half minutes. In the case of slight over-exposure up to about four times the normal, the time of development may be reduced to not less than half; for exposure of more than four times correct, the development should be one and a half minutes at 60 deg., or one minute at 70 deg. F. For still greater over-exposure the composition of the developer may be modified, using about twice the pyro and half the ammonia, and developing for six and a half minutes. In the case of under-exposure the time of development may be doubled, or, in cases of great under-exposure, the pyro halved, the ammonia doubled, and the time of development increased to six minutes. The full text of MM. Lumière's paper will appear in our columns at an early date.

**THE PHOTOGRAPHIC CLUB.**—Mr. A. Corbett informs us that he has been elected hon. secretary and treasurer, and requests that all communications be directed to him to 9, Riffel Road, Willesden Green, N.W.

## SOME NEW FACTS OF STAND DEVELOPMENT.

[The following paper, just issued as a circular by Messrs. Wratten and Wainwright, will be seen to contain the results of experiments made in the firm's research laboratory on this method of development. Messrs. Wratten's experiments show that dilution of a developer to, say, one-tenth strength, does not prolong development ten times, but that the time required with the weak stand developer varies according to the quantity of air dissolved in the water. Glycin is found to be least subject to irregularity from this cause. Messrs. Wratten also point out the necessity of precautions to avoid fog and markings during the necessarily protracted period of "stand" development.—Eds. "B.J."]

A METHOD of developing plates which always appeals by its apparent simplicity and economy, is that which is known by the name of "Stand development." For convenience we write of "Stand development" in the sense described below. By "Time development" we understand development for a fixed time with a developer of about the normal strength. "Time development," as users of our plates know, is advised by us in the case of colour-sensitive plates. In "stand" development the plates are placed in a grooved tank with a dilute developer, and are left to soak until finished. At first sight this method seems easy, and at the same time, owing to the dilution of the developer, economical—in actual fact, however, we doubt whether it is either.

It can scarcely be considered economical in the first place, because the tanks made for the purpose, ingenious and convenient as they are, require a very large quantity of developer; one of the smallest, for instance, requires 29ozs. of developer to develop six half-plates; and after a development lasting for half an hour the developer would be so oxidised that it would not be advisable to use it a second time; so that the claim of economy can scarcely be justified.

### A Fallacy of Stand Development.

It must also be remembered that in dealing with "stand" development we cannot go away and leave the plate to develop itself for an indefinite time any more than one can with any ordinary development. If a plate would require 3 minutes in an ordinary developer, and 30 minutes to give the same result in a "stand" developer, then if it were left for an hour in the "stand" developer it would be just as much spoiled as if it were left for 6 minutes in the ordinary developer; so that it is essential with stand development to know the time which the development will take.

### Weakened Developer Needs Disproportionately Longer Time.

Inasmuch as we recommend time development with our colour-sensitive plates, a large number of the users of those plates have adopted "stand" development, and have appealed to us to give them the time which developers of various formulæ should take. At first sight it would appear to be a simple thing to give this time:—Suppose, for instance, that the metol-hydroquinone formula which we recommend on the cards enclosed in our plate boxes, requires 5 minutes for development, then it might be supposed that if this developer were diluted 10 times it would require 50 minutes for development, or that, at any rate, if it did not require 50 minutes for development, we could give the amount it did require; such, for instance, as 15 times instead of 10 times the time given on the cards. We were, however, aware that probably influences which were not obvious would disturb this conclusion, and we have recently made an investigation of the question, and have obtained the following results:—

We used for our experiments rodinal, glycin, and pyro-soda developers, abandoning metol-hydroquinone, which did not seem to us suitable for "stand" development on account of its easy oxidation. Rodinal is largely used for "stand" development, and we commenced our experiments with this.

### The Reason: Oxidation by Dissolved Air.

A plate was developed for 3 minutes in 1 in 20 rodinal. Rodinal was then diluted to be 1 in 200, and other pieces of the same plate were developed in it, the time being found which was necessary to give the same result. If the developer were diluted with distilled water which had been freed completely from air by means of a vacuum pump, the time of development required was not 30 minutes, as would be calculated from the dilution, but 42 minutes. If it were diluted with recently distilled water, which is as free from air as any that can be generally obtained, the time of development was 46 minutes, while if it were diluted with ordinary tap water, the time of development was 53 minutes.

From this it will be seen that it would not be possible to give any factor by which the times we give for 1 in 22 rodinal could be multiplied if the rodinal were diluted 10 times, because the time of development would depend entirely upon the amount of air dissolved in the user's water; an amount beyond our knowledge or control. We therefore experimented with glycin and with pyro-soda, and found that neither of these developers were sensitive to air in the water. They took the same time to develop the plate whether they were diluted with absolute, air-free water, or with the ordinary tap water; we found, however, that if pyro-soda were diluted 10 times from our usual formula, it took not 30 minutes to produce the same result as was produced by the strong developer in 3 minutes, but 41 minutes. So that if the pyro-soda developer which we give be diluted 10 times, then the time of development must be multiplied by 15. This peculiarity was not shared by a glycin developer, and we consider this the most satisfactory for use in "stand" development. To sum up:—

### Two Recommended Formulæ.

If a pyro-soda formula be diluted 10 times, the time of development should be increased 15 times; the following formula requires 15 times the time of development given on the cards with the plates.

#### PYRO-SODA.

(1) Sodium sulphite .....	100 gms.	6 oz.
Pyro .....	17 gms.	1 oz.
Sulphuric acid .....	2 ccs.	1 dr.
Water .....	10,000 ccs.	600 oz.
(2) Sodium carbonate .....	100 gms.	6 oz.
Water .....	10,000 ccs.	600 oz.

Take equal parts of 1 and 2.

For glycin we recommend the following formula, which will require 10 times the time of development given on the plates:—

#### GLYCID.

Glycin .....	9 gms.	$\frac{1}{2}$ oz.
Sodium sulphite .....	27 gms.	1 $\frac{1}{2}$ oz.
Potassium carbonate .....	46 gms.	2 $\frac{1}{2}$ oz.
Water .....	10,000 ccs.	600 oz.

We do not recommend metol, rodinal, or metol-hydroquinone, on account of the difficulty with air in the water. May we also point out that though the experience of our research laboratory is at the service of all our correspondents, yet we cannot undertake to give times of development for special formulæ, unless the result is likely to prove of general use and interest.

### Tank Markings and Fog.

Another point to which we wish to call attention relates to the defects arising from general fog, and from edge markings, in plates developed in "stand" development tanks. A plate during development is peculiarly susceptible to fog, as much so at any period of its existence, and particularly to chemical action, so that the long development time of a stand-developed plate always tends to produce a danger of fog. In tanks made of zinc, the zinc may not only be attacked by the chemicals used, but may itself also fog plates. All bad air, fumes of turned gas, stagnant water, and the multitude of chemical impurities in the air and solutions of a badly ventilated and not always thoroughly clean dark-room, will unite to attack plates which are soaking in a developer, whilst tanks, which are also used for the purpose of fixing, are always liable to the suspicion of hypo contamination. It may be pointed out that the developers given here contain no bromide. The addition of a small quantity of bromide will generally diminish any slight trace of fog, but when using bromide it must be remembered that for moderate amounts of bromide the time of development should not be altered, but the time of exposure must be increased;

that is to say, a plate which is to be developed in a bromided developer will require a somewhat fuller exposure than one to be developed in an unbromided developer.

Edge markings are frequently accompanied by a lack of gradation in the high-lights. The cause of the edge marking and the lack of gradation is the same; it is that in many of the tanks on the market the plates are too close together, and are too close to the bottom of the tank; the result is that the plate is to a certain extent starved of developer, so that the development progresses more rapidly in the half-tones and shadows than in the high-lights of the plate, producing a flattening of the high-lights; while the marking on the lower edge is caused by the solution of the backing which falls to the bottom of the tank and accumulates on the lower edge of the plates, the backing from one plate affecting the face of the plate immediately behind it.

This can be to some extent prevented by placing all plates face to face and back to back in pairs in the tank.

In conclusion, we do not as a general rule recommend "stand" development, though it is sometimes convenient, but if it is desired that it should be used, then the details given here will probably prove of service.

## ARTIFICIAL LIGHTS IN PHOTOGRAPHY.

### III.

Increase of the arc can be produced by increasing the current or by using "effect" or impregnated carbons. For printing, only those impregnated carbons which give a white light should be used, as the others are too poor in blue and violet rays. If coloured originals have to be copied and a light approximating to daylight desired, then the output of the lamp should be increased by the use of impregnated carbons.

An extremely effective form of lamp, which gives a wide field of very even illumination, is that in which the carbons, instead of being

the illumination of a plane,  $FF$ , we have the "illumination curve,"  $K$ .

If a sheet of paper is laid below the lamp it will be found to blacken fairly symmetrically around the axis of the lamp—that is, round the perpendicular dropped from the arc through  $O$  to the plane, and the greater visual luminosity of the positive crater can hardly be detected. The photo-chemical luminosity is chiefly due to the arc itself, but the light of the carbons flattens the curve and makes it more even. With such a lamp one may use a cone of nearly

Fig. 9.

one above the other, are both directed downwards at an angle of about 30deg., and are enclosed in framework,  $C$  (Fig. 9), which becomes partly magnetised, and blows the arc out into a flame of about 1in. in length. In this form the positive crater is of minor account, the bulk of the light being actually resident in the arc itself.

From Fig. 9 it will be seen that the light is directed downwards and outwards over an angle of 160deg., though the maximum of visual luminosity lies in the direction of  $r$  from the positive crater. The intensity curve is compounded of that of the arc and that of the positive crater.  $C$  (Fig. 10) shows that of the former and  $C_1$  that of the latter, so that the final intensity curve becomes  $C_2$ , and for

Fig. 10.

50 deg. for half-tone negatives and almost 60 deg. for those in line. It may be assumed that at a distance of 20in. a circle of about 18in. to 24in. diameter is sufficiently evenly illuminated. Sixteen inches is about as near as one can get to the lamp on account of the great heat evolved, though very short exposures may be made at 10in. A sheet of paper exposed at this distance gave a dark area of 155 square inches.

Testing the lamp, as in previous cases, by printing with and without a sheet of glass, the light was found to contain about 33 per cent. of ultra-violet rays.

The framework,  $C$  (Fig. 9), which is called an "economiser," practically acts not only as a reflector, but produces a partial vacuum, or, rather, a space in which there is less oxygen; therefore

the consumption of the carbons is minimised. As a reflector it increases the light by about 30 per cent. Naturally a glass globe must also be used if the full effect of the "economiser" is to be obtained, otherwise there would be diffusion of the air into the space of the "economiser."

### The Enclosed Arc.

This type of lamp has lately found much favour. As very high voltages are used, it is necessary to enclose the carbons in a practical vacuum, otherwise they would burn away very rapidly and glow throughout their whole length.

There is no crater, but the two poles are flat at the ends, and the arc wanders round and about the surfaces (Fig. 11). The positive + pole, however, emits the most light, the negative—pole remaining comparatively dark. The arc *b* (Fig. 11) is over an inch long, and emits an intense violet light, which is increased by the white glowing positive pole.

It is extremely easy to see visually the "illumination curve" of the positive carbon and that of the arc by holding a sheet of white paper parallel to the lamp. The former is intensely white, whilst the violet zone is comparatively dark. On the other hand, by replacing the white paper by a sheet of collodion P.O.P. an almost even tint is obtained, the more powerful photo-chemical ultra-violet rays evening up the action.

The higher the voltage the richer in ultra-violet, and comparatively

Fig. 11.

poorer in the less refrangible rays the arc becomes; therefore this lamp is not suitable for copying coloured objects on colour-sensitive plates. A yellow filter will increase the exposure about five times more than usual, or more still the lower the voltage.

In consequence of the great separation of the carbons, the arc emits its light almost without hindrance, and as it constantly changes its position it acts like a circle of light of about 1 in. in diameter, if we take into consideration only an angle of about 20deg. on each side of the central horizontal line.

The "illumination curve" is therefore somewhat flatter than that shown in Fig. 3 for a surface parallel to the carbons. The homogeneity of the light is about equal to that of the lamp just previously described, and for half-tone negatives a light cone of about 40deg., and for line one of about 60deg., can be utilised.

A sheet of collodion paper, exposed at a distance of 10 in., gives an almost circular spot of 155 square inches.

Testing this lamp, as in previous cases, it was found that a sheet of collodion paper was blackened to the standard tint at a distance of 20 in. with

A 4-ampere lamp in .....	70 seconds;
A 6-ampere lamp in .....	33 seconds.

The interposition of a sheet of glass  $\frac{1}{4}$  in. thick only increased the time by about 10 per cent. This is, of course, explained by the fact that the glass cylinder surrounding the lamp absorbs the greater part of the ultra-violet rays.

An enamelled white reflector of the shape shown in Fig. 12 about doubles the light, and the standard tint was obtained in 16 seconds. At a distance of 20 in. a negative prints three times as quick, or six times with the reflector, as in diffused daylight, and as a cone of

from 40deg. to 60deg. can be used, it is possible to print a negative 24 in. by 16 in. at this distance.

The high efficiency of the reflector is probably due to the fact that the whole of the rays emitted by the lamp are collected and reflected, so that it acts as a large reflecting surface.

### THE TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.

READERS of the daily press will have read of the installation of part of the "Daily Mirror" of Professor Korn's method of electrical transmission of half-tone photographs. Last Thursday a large company of journalists and others assembled at the "Mirror" office to witness a demonstration of the use of the

Photograph cabled to the *Daily Mirror* from Paris, November 8, 1907.

between London and Paris for the telegraphing of a photograph. Professor Korn himself delivered a short lecture, and did his best to make clear the highly technical method employed under the system. The results, which have been reproduced in the "Mirror," show the complete sufficiency of the Korn process at the present time for the purposes of the illustrated newspaper. They are a prising advance on those which were shown to us in London some five years ago by Professor Korn with the aid of an experimental installation, which we believe was the first to be used outside Professor Korn's own laboratory at Munich. As regards the electrical methods adopted by Dr. Korn, we must refer our readers to the issues of the "B.J.," in which they have been described at length.

### Other Methods.

Writing of the telegraphic method of M. A. Belin, the "Daily Telegraph's" Paris correspondent says that the apparatus is different from that of Professor Korn, but is equally efficient. M. Belin does not employ selenium, which, according to him, has a particular drawback. His transmitting apparatus is a cylinder, on which is wound the photograph, which is in slight relief. As the cylinder revolves, a needle follows the surface of the photograph in spiral lines, the distance of a sixth of a millimetre apart. The needle is carried by a level, which oscillates more or less according to the movement of the former, which, being connected with the transmitting wire, causes the intensity of the current to vary correspondingly. The receiving apparatus carries another cylinder, revolving at exactly the same rate, round which is wound a sensitive film. An "oscillograph," consisting of a loop of the finest wire, through which the current passes, and which bears a tiny mirror, one millimetre long by seven-tenths of a millimetre wide, transmits, by means of an electric lamp, rays of light to a lens. The wire loop is more or less twisted, as the current varies in strength, and the mirror is thus more or less deflected from its original position. The lens directs the rays through an aperture in a screen on to the cylinder and the film. Each movement of the needle in the transmitting apparatus thus exactly corresponds

to a movement of the mirror at the other end, and the rays of light thrown on the receiving film vary correspondingly in intensity. As the needle follows the original photograph very closely, the reproduction obtained is proportionately accurate.

The Paris "Journal" also reports that an inventor, M. Berjonneau, has constructed a new tele-photographic apparatus, by which pictures may be transmitted to any distance by means of submarine cables. It is thought that it will even be possible by means of this apparatus to send pictures by wireless telegraphy.

## Photo-Mechanical Notes.

### Section-Cut Half-Tone Screens

ACCORDING to a recent specification (No. 58, 1907), a patent has been taken out for a process of preparing half-tone screens by cutting a section of cemented celluloid films. The patentee, Robert Krayn, 24a, Marien Strasse, Berlin, employs the following method:—

The layers or bands are piled up until a sufficiently thick block is produced, from which the veneers can be cut transversely and then be polished on both sides. The number of lines of these screens or veneers depends on the number of the layers piled up in the block. In order to produce cross screens two or more of such screens are cemented crosswise on to each other, and are then cemented between two sheets of glass.

Single plates are then placed one upon another until a block of the required thickness is obtained, the plates being coated with the cement before putting them together. The plates thus assembled are then exposed to a strong hydraulic pressure, which unites them in a homogeneous block, which is cut into sections.

In case the sections obtained as described above are piled up one upon another in such a manner that the transparent lines of one section lie over the opaque lines of the layer beneath it, and are then united again so as to form a block, which is again cut into sections which are vertical to the primary section of which it is composed, a veneer would be produced, which would have the appearance of a chess-board consisting of transparent and impervious squares, but it is nearly impossible to realise so exact a fitting over each other of the different lines of the primary section. If the lines do not fit exactly over each other, squares will also be obtained, but same will be seemingly irregular form, which might have an advantageous effect on the picture or photograph. The screen can be employed as a direct support to the sensitive plate. The exposure to light takes place on the back part through the screen. The negative thus obtained is adapted to be directly employed for half-tone work.

If layers of the thickness of the well-known roll film (0.05 mm.) are employed twenty layers or lines are obtained in each mm. thickness. If from such a block sections 0.05 mm. thick are sliced or peeled off and a new block is formed of these sections, which is cut vertically to the primary section, of which it is composed, films are obtained of the character of a chess board with 400 squares to the square millimetre, of which 200 are transparent and 200 impervious to light. For the etching process, of course, these squares are too small.

If the film, however, is covered with the sensitive plate and the back exposed to the light, a negative is obtained, the positive copies of which display the character of etchings, this effect being caused by the dissection of the shadow and half-tones into fine points.

Instead of pasting the single bands on to each other, this colourless transparent and impenetrable layers of quickly drying collodion or other suitable material may be poured or placed one upon another until a block is formed, or the different plates are produced, of which the block may then be composed.

**TELESCOPIC LENS HOOD.**—Those who recognise the value of shading a lens—and the practice is one which is an almost necessary precaution in the case of the modern air-spaced anastigmat—will be interested in hearing of a new lens hood which is being introduced by Messrs. A. E. Staley and Co., of 19, Thavies Inn, Holborn Circus. The hood is telescopic, and forms, when opened out to its working position, a series of concentric diaphragms. The accessory, as soon as it is ready, should be sure of a large sale.

## Exhibitions.

### HACKNEY PHOTOGRAPHIC SOCIETY.

When, after traversing the wilds of Shoreditch, we reached the public baths of Hackney, we found Mr. Walter Selfe in person admitting the burgesses of that borough to the exhibition hall at sixpence a time all the afternoon; after 6 p.m. entrance costs one shilling, but for that sum one gets a two-hour concert and a lantern lecture, besides the privilege of examining 499 (see catalogue) specimens of modern photography. That is the Hackney plan, eminently practical of gilding the photographic pill and inducing the astute Hackney public to come in its hundreds and gulp it down, concert and all, at the ridiculous figure of one shilling per head. As a local function the exhibition is a pronounced success, thanks to the tireless energy of Mr. Walter Selfe, who for years past has guided the Hackney Society on a prosperous and solvent course. As a consequence the members of the Society are able to pride themselves on bringing together a collection of their own and others' work which ranks very high among photographic exhibitions. Moreover, the members' classes compare very favourably with those open to general competition. If any criticism be levelled at the Hackney work as a whole, it is that the members show too evident a desire to trim their sails to the mood of the moment in pictorial photography. To accuse any of them of playing up to the judges is to credit them with more than human cleverness, seeing that Mr. A. H. Blake judged with Mr. H. W. Bennett and Mr. Furley Lewis. There was, however, rather more of the "mist-and-mirk" sort of photograph than one is accustomed to look for in an exhibition largely contributed to by Mr. Hensler, Mr. Rawlings (not the "oil" Rawlings) and Mr. Selfe.

Of the work awarded in the "Portraiture and Figure Study" class we preferred Mr. F. E. Roofe's clever little Dutch picture (No. 21) to Mr. Hensler's "Habitué" (No. 27) in St. Paul's Churchyard. The pigeons which he feeds are too much of a tone with the habitué, with the result that the difference in personal cleanliness between the two classes of beings disappears. Mr. Roofe's "Little Curly-Locks" is another delightful child study.

Mr. Selfe's "Across the Thames at Low Tide" (No. 56), which is judged best in all Members' Class, is splendid photography, but all too warm in tone for the Thames at Somerset House. No. 101, by Mr. C. J. Powel, interested us for its demonstration of how a print 2in. x 1½in. is nevertheless strong enough for an exhibition wall.

In the largest Members' Class, "Landscape and Seascapes," the award to Mr. Rawlings goes to No. 108, "The House on the Hill," which perspectively is a very clever piece of work, but is not as good as the average of Mr. Rawlings' work in composition. The interest is placed in the top quarter of the picture, but at the cost of weakening of the foreground. Mr. Hensler's rendering of a "Wet Night in Suburbia" (No. 144) is a very clever night picture, with all the effect of light on water-laden air. His "Mist Lifting," No. 145, is also a fine rendering of mist over a panorama, and would be beautiful but for the coarse texture of the paper. The third award goes to a gum print, but the puzzle of the section is Mr. H. W. Lane's picture of St. Paul's and some scaffolding, which is entitled "Tugging."

Mr. Selfe takes a deserved award in the Architecture Class for his "In a Ruined Church" (No. 9), fine technical work, with the feeling of the deserted shrine in it.

The Open Classes are not up to the standard which Hackney usually secures outside its own ranks. No. 277, which is judged the best in all the Open Classes, is a clever effect of lighting on the figures of potato diggers, by H. Y. Simmons. Mr. Judge's "After a Storm" is a fine piece of work which does not gain an award. No. 367, which does, is in the big style, and has a good rendering of motion in it. In the Miscellaneous Class, to which "Animals, etc.," are relegated, Mr. Henry J. Comley takes the award for a three-colour carbon, "Dessert."

The representation of colour photography by the newer screen-plate processes is limited to about half a dozen Autochrome transparencies by Messrs. C. Welborne Piper and John H. Gear, together with a couple of examples of the Warner-Powrie process. In the trade section, the exhibitors are Messrs. R. and J. Beck, who receive the trade award for the "Isostigmat" lens; Messrs. Burroughs, Well-

come and Co., who show results of a new universal developer, "Rytol," and examples of the 1908 "Wellcome Exposure Diary"; Messrs. C. P. Goerz, Wellington and Ward, and the White Band Chemical Co., in addition to the local exhibitors, Messrs. F. F. Dadd and Son, Grant and Taylor, and William Rawlings and Co.

#### FORTHCOMING EXHIBITIONS.

- November 5 to 27.—West of England Industrial Exhibition (Photographic Section). Sec., A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.
- November 12 to 16.—Rugby Photographic Society. Sec., R. H. Myers, 13, Bridget Street, Rugby.
- November 19 to 23.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.
- November 25 to 28.—Lancaster Photographic Society. Entries close November 16. Sec., Walter Gunson, Manesty, Scoforth Road, Lancaster.
- November 20 to 27.—Croydon Camera Club. Sec., H. T. Dodsworth, Enmore House, Woodside Green, South Norwood.
- November 28 to December 4.—Southsea Photographic Society. Sec., Gilbert Wood, 10, Pelham Road, Southsea.
- December 5 to 7.—St. George Co-operative Society Camera Club. Entries close November 25. Sec., George Anderson, 77, Brae-side Street, Glasgow.
- December 5-7.—North London Photographic Society. Entries close November 30. Sec., C. H. Madden, 12, Dagmar Road, Stroud Green, London, N.
- December 11 to 14.—Hove Camera Club. Sec., Stanley Read, 12, Old Steine, Brighton.
- December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

- February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.
- February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

#### CATALOGUES AND TRADE NOTICES.

**BOARDMAN ARC LAMPS.**—The Boardman Co. of 10, Southwark Bridge Road, S.E., send us their new list of open and enclosed arc lamps for portraiture and printing. It includes particulars of the firm's complete portrait and printing outfits at £14 14s. and £10 10s. respectively.

**COLLOTYPE POSTCARDS.**—Some excellent specimens of colotype postcards in monochrome and colour are sent to us by the Barton Pictorial Postcard Co., Ltd., 15, St. James', Barton, Bristol. The firm's work should appeal to photographers requiring a really good series of cards at a moderate price.

**THEFTS BY TRAVELLING PHOTOGRAPHER.**—A photographer named Harry May was, at South Shields, last week, committed to the Quarter Sessions for trial on three charges of theft from landladies at whose houses he had stayed. It was stated that accused was wanted at Sunderland and West Hartlepool.

**TO AVOID "COCKLING"** when mounting prints upon their papers, as in "multiple" mounting, Mr. W. Brush, in addressing the Bristol Photographic Club, advised making pin-pricks on the mounting paper exactly where the four corners of the print were to come. Then with a sharp knife making two diagonal cuts, like the letter X, nearly, but not quite, joining each pair of diagonally opposite pin-pricks. The edges only of the print are then smeared with the minimum amount of some adhesive containing but little water, such as Secotine or one of the photo-pastes, and the print quickly pressed on to the mount so that its corners agreed with the pin-pricks. The same procedure is gone through with any subsequent thin mounts the print may require.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between October 23 and November 2:—

- MULTI-COLOUR FILTERS.**—No. 23,738. Improvements in yellowish light filters for polychrome exposures. Ernst Wandersleb, Jena, Germany.
- TONING AND MOUNTING.**—No. 23,762. Process for photographic toning and mounting. Harry Schmidt, 509, East Street, N.W. Washington, D.C., U.S.A.
- ONE-PLATE COLOUR PHOTOGRAPHY.**—No. 23,812. Process to reproduce in natural colours, transparencies, positives, and enlargements, from a single negative and single exposure. James Marlow Child, 27, Harrington Street, Pear Street, Derby.
- OPTICAL LANTERNS.**—No. 23,818. Improvements pertaining to optical lanterns and the regulation and control of light-producing agents, electric arcs, limelights, or the like, used in connection therewith, and apparatus therefor. George Robson, 21, Rochdale Road, Leyton, Essex.
- ANTI-HALATION DEVICE.**—No. 23,962. Improvement in lighting fixtures for taking non-halo photographs of interiors. Max Anzinger, 224, Friedrichstrasse, Berlin, Germany.
- PLATES.**—No. 23,964. Improvement in arrangements in covering photographic plates for partial exposure. Hans Steindl, 224, Friedrichstrasse, Berlin, Germany.
- DEVELOPMENT.**—No. 23,973. Improved device for holding flat-plate photographic films during the processes of development. Benjamin Thomas Akers and John Edward Wilson, 33, Chancery Lane, London.
- PRINTING PROCESSES.**—No. 24,124. Improved gelatine compound for use in photographic printing processes. George Edward Hawke Rawlins and J. J. Griffin and Sons, Ltd., 322, High Holborn, London.
- CINEMATOGRAPHS.**—No. 24,157. Improvements in film gates for cinematograph machines. Leo Kamm, 27, Powell Street, Goswell Road, London.
- REPRODUCTIONS ON GLASS, ETC.**—No. 24,214. Improvements in or relating to the reproduction of images on glass, porcelain, ceramic, metallic, or other surfaces. Maurice Anthès and Edwin Lloyd, Ltd., 70, Chancery Lane, London.
- CINEMATOGRAPHS.**—No. 24,225. Improvements in or relating to incombustible cinematograph ribbons or strips. Frederic I. Mare, 72, Cannon Street, London.
- MULTI-COLOUR SCREENS.**—No. 24,233. Improved means for the manufacture of photographic multi-coloured line screens. Alfred James Munro, 43, Southampton Buildings, London.
- FOCAL-PLANE SHUTTERS.**—No. 24,240. Improvements in "focal plane" shutters for photographic cameras. Wilfred Bailey, 1, St. Ann's Square, Manchester.
- PRINTING FRAMES.**—No. 24,285. Improvements in photographic printing frames. Frederic Cotton Symonds, 56, Ludgate Hill, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FOLDING REFLEX CAMERAS.**—No. 16,198, 1906. The invention consists in improvements to the camera described in Patent No. 21,561, 1903, first in regard to providing means for lifting the mirror into position behind the focussing screen. This is done by mounting an arm upon the spindle or one of the pivot pins upon which the mirror is carried, and connecting this arm by means of a link with a slide. The slide may engage by means of a spring-operated catch so that it may be retained by the catch in the position corresponding to the uplifted position of the mirror. The slide moves by means of a stop mounted so as to protrude on the outside of the frame, and the catch may be adapted to be operated for release from without. Means are also provided for mounting the hood of the camera, for ensuring

the fall of the focussing screen before the closure of the camera, and for fixing the mirror in relation to the focussing screen. Charles Edmund Peczenik, 11, Pancras Lane, London, E.C., and Augustus John Gratte Maskens, 12a, Cross Street, Islington, N.

**MULTIPLE CAMERAS.**—No. 6,739, 1907. The claim is for a camera of the form shown in the figure, in which four separate lenses are employed, the four dark slides being placed at *f*, *g*, *h*, *i*. The advantage of the spherical photographic apparatus is stated to lie in the fact that both in separate and combined exposures

the views are taken at the same angle, while the adjustment of all the objectives, both laterally and vertically, can be uniformly and simultaneously effected from a central point. Robert Bachstein, 17, Dürerplatz, Dresden, and Balduin Emil Enge, 22, Kronprinzstrasse, Oberlössnitz, Germany.

**PLATE-HOLDERS.**—No. 6,613, 1907. The invention is for a plate-holder, consisting of a bent sheet with open base and sides,

partially cut away. It is provided with stops, 4 and 5, for the purpose of holding the plate in position. Michael Paris Foran, 38, Portland House, Johannesburg, South Africa.

**UNIVERSAL CAMERA.**—No. 12,662, 1907. The claim is for "a camera for photographic and optical purposes, comprising a screen room; a lens box mounted externally of the screen room and opposite an aperture in the front wall thereof; a guide frame supported independently of the screen-room structure and adapted to enable a lens box to be shifted for the purpose of adjusting the focus of the lens; a copy board supported by and adjustable lengthwise of the guide frame; bellows connecting the lens box with the aperture in the screen room; and means for enabling the lens box to be adjusted lengthwise of the guide frame from within the screen room."

The essential feature of the apparatus appears to be the building of the camera of such size that the operator can enter it and carry out focussing, vignetting, etc., while within it, at the same

time being able to make the adjustments of the lens, etc., which are outside the camera-chamber. Alchanan Cohen, 8, Nicholas Street, St. Peter's Road, London, E.

**CHANGING BOX.**—No. 22,994, 1906. The invention relates to a changing box of the form shown in the figure, in which *a* is the outer box or casing, *b* is an inner case which slides into the outer casing *a*. This latter case *b* contains the plates *c*, each plate being carried in a sheath *d*. The top end of the sheath is turned over at *e* so as to form a wedge or bevel. The other end *f* of each of the sheaths is also turned out so that it is approximately parallel with the surface of the wedge *e*. Each of the sheaths *d* is provided with a projection or stamped-up portion *k*. *g* and *h* show light-buffers placed at the top and bottom of the outer casing *a* and the inner casing *b* respectively. *m* and *n* are stops provided respectively on the outer casing *a* and inner casing *b* so as to prevent the latter being pulled entirely out of the former.

In using the apparatus the casing *b* is drawn down and the spring *s* taking against the catch *k* on the sheath *d* at the back of the casing *b* prevents the said sheath *d* being drawn down with the rest of the sheaths, so that when the other sheaths are drawn down sufficiently to clear the sheath thus held by the spring *s*, this sheath is pressed forward against the window at the front of the box *a*, as shown in the frame. The photograph is now taken, and then the inner casing *b* is pushed upwards. The wedge portion *e* at the top of the sheath next to the front, as it rises, will slide over the inclined surface *f*, and, when the casing *b* is pushed completely in, the plates will be in their original position except that the plate which was formerly at the back of the box next to the spring *s* is now in the front of the box, so that when the operation is repeated the next plate towards the back will be brought up ready for exposure. When the plates are all exposed he entire case may, if desired, be immersed in a developing bath, the developer being allowed to enter the case and flow over the plates by the apertures protected by the buffers *g* and *h*. The other operations, such as washing, fixing, or the like, can also be performed without removing the plates from the sheaths or the box, so that on completing the operations it is simply necessary to remove the finished negatives from the sheath. Robert Barr, Hillhead, Woldingham, Surrey.

**PRISMATIC DISPERSION COLOUR PHOTOGRAPHY.**—No. 8,723, 1907.

The inventor proposes to employ the following process:—

The optical image of any subject is first decomposed by means of a screen into a large number of parts which are very small relatively to the size of the image. In their further course the rays of light of these small parts enter a colour-diffusing device 2, which may consist of a simple prism, a direct-vision prism, any combination of prisms, a combination of small particles of colour-diffusing material, a diffraction grating or the like. By means of the colour-dispersing device the parts of the image are dispersed into small more or less pure, real, or virtual colour spectra, so that the image received on a ground-glass 3 or the like consists of a large number of very small spectra, which, however, in consequence of their smallness, can scarcely be perceived as such, and which give the impression of the original image.

If the ground glass 3 be replaced by an ordinary panchromatic plate or the like, each colour of the object to be photographed will act in those places in the sensitive layer, in which it has, in the small spectra, the position corresponding to its wavelength. For example, if the parts of the image passing through the screen at 4 consist of the colours yellow and green, action of the light will only take place on the particular similar-coloured places of the entire spectrum.

If the negative produced in this manner be placed in the posi-

tion of the ground glass and observed against a white surface arranged in front of the screen, those colours which had acted appear hidden in the surface of light consisting of complete

spectra. On the other hand a positive produced from the negative allows only these colours to pass through and the image appears in the proper colours.

The image may also be projected or the apparatus may be combined with a stereoscopic apparatus or the like. Moreover the image can be copied by various copying processes or by employed for producing the parts of the image for three or more colour-processes, different areas of colour being excluded alternately in the copying by screens which cover these colours, or by colour filters, or positives produced therewith, having a surface on which the smaller spectra are reproduced by any process whatever, may be interposed, or the copying be effected on colour printing paper in a copying-frame furnished with a colour-screen corresponding to the spectra. The apparatus furnished with this contrivance is likewise suitable for ordinary monochrome photography and when properly fitted up for taking photographs by fixed waves of light. Franz Urban, Hotzenplotz, Silesia, Austria.

**CINEMATOGRAPHS.**—No. 3,119, 1907. The invention consists of a rotary film-mover in which the engaging finger is adapted to be moved in a direction at right angles to the path of the film to disengage the finger from the same. Enoch J. Rector, 131, West Twenty-fourth Street, New York City, U.S.A.

### New Trade Names.

**ANGELO.**—No. 296,599. Photographic printing papers. The Eastman Kodak Co. (a corporation duly organised under the laws of the State of New York, U.S.A.), 183, Main Street East, Rochester, New York, U.S.A., dealers in photographic materials September 26, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Controlling Contrast in Bromoil Printing.

In bromoil (says a writer in "The Photographic News") the contrast is controlled in two ways, either by the strength of the original bromide print or by the adjustment of the quantities of alum and citric acid mixed with the ozobrome solution. Of course, the variations of ink and manipulation in pigmenting apply as well to the bromoil as to the original oil process. The best results are to be obtained by the use of a normal bromide print, fully developed, so that the deposit of silver is adequate, and then a careful balancing of

citric acid and alum to give the desired result. An excess of alum will give flat prints on pigmenting, while less alum gives an increase of contrast, and the citric acid may be maintained in constant quantity.

### Toning Platinotype with Sumach.

A method of toning platinum prints (writes Mr. C. Ainsworth Mitchell in "The Amateur Photographer") is to treat them for about fifteen minutes with a hot solution of a vegetable extract containing one of the so-called "iron-greening" tannins, such as Sumach extract which can be obtained as a commercial article. About a teaspoonful of the extract is dissolved in a pint of water at about 140 deg. Fahr. and the print immersed in the liquid until sufficiently toned, after which it is washed for a few minutes in tap water and dried. The tannin combines with the traces of iron left in the paper after the acid bath, and the print is changed to a soft greyish green colour and is also intensified to some extent. Chestnut bark extract has a similar toning effect, though the colour is less pleasant than that produced by Sumach.

## New Books.

"Jahrbuch für Photographie und Reproduktionstechnik," 1907. Edited by Dr. J. M. Eder. (Halle: W. Knapp. 8 marks.)

This year's issue of "Eder's Jahrbuch" reaches us rather later than its appointed time of publication, yet we can appreciate, perhaps as well as anybody, the labours which must precede its completion for the press, and are ready to pardon its delay in reaching us, so long as we are able to add it to the series of volumes on our shelves, the value of which, for reference purposes, we cannot easily exaggerate. Dr. Eder's compilation shows no radical departures from previous issues of the "Jahrbuch." The volume opens with a series of papers by Continental authorities. Notable among these are Dr. W. Scheffer's note on a general formula for stereoscopy, General Obermayer's review of recent progress in colour photography, Dr. T. Dokulil's précis of stereoscopic progress, and Dr. E. Wandersleb's interesting paper on the variation of distortion with various lenses when used copying on various scales of reduction.

In the systematic résumé of the photographic literature of the year Dr. Eder exhibits his genius for prolific and careful abstraction. If it is too profuse, say, in reproducing details of apparatus, the fault, a good one, and he is to be commended when he adopts copious short references in the case of the more recondite themes of scientific photography. We do not find quite the accustomed number of editor's comments on the more questionable items of alleged fact, but the volume, as a whole, shows that the editor and his staff not less painstaking in their orderly collection of the work of the year which worthy of record. The usual indexes, one of names and the other subjects, is as full as ever. The only suggestion towards improvement we can make is that in the names-index some indication of the subject of each entry should be given in cases where there are a number of entries to a given name.

"Denizens of the Deep." By F. Martin Duncan, F.R.P.S. (London: Cassell and Co.) 5s.

A new book of nature-wonders, "presented," as Mr. Frohman would say, by the camera. Mr. Kearton and Mr. Pike have lain on the earth or ascended to its dizzy heights. Mr. Martin Duncan takes his readers to the waters that are under the earth, a very interesting tale he spins of the strange folk to be encountered there, their habits and proclivities, and their (frequently reprehensible practices and their quaint moral conventions. The latter, it should be added, are chiefly introduced or implied by the author for the picturesque effect; the glimpses of deep-life à la mode, however, even if they are imaginative, are all the good of the story-book, and usually, it must be admitted, Mr. Duncan is not without some experimental support for his humorous conception of submarine amenities.

The barnacle spends its later life standing on its head. The crab leads the strenuous life when young; the sea-anemone may devour him, but as soon as he is grown up he is able to resist

out a claw into the stomach of his former foe and remove any delicate morsel which the anemone may be digesting. The female octopus is a model mamma, and jealous of her offspring to the degree of devouring her own spouse should she suspect him—as she may with good reason—of designs upon the little ones.

It is because Mr. Martin Duncan has the rare gift of writing thus humorously of the underworld of Nature as he has seen and photographed it, that his book, with its sixty odd illustrations, is a delightful Christmas present for a boy or girl.

"Photographische Probleme." By Dr. Lüppto-Cramer. (Halle: W. Knapp.) 2 marks 50 pf.

Dr. Lüppto-Cramer's continuous papers on phenomena involved in emulsion-making do not lend themselves to condensation. Yet the experimental results which they contain may be sufficiently valuable to make it worth while keeping the full texts of the papers at hand for reference. This volume, therefore, the fifty-eighth of Herr W. Knapp's "Encyclopädie der Photographie," should be a useful addition to the chemical literature of photography.

"The Patents and Designs Act, 1907." By J. Roberts and H. Fletcher Moulton. (London: Butterworth and Co.) 4s.

The recent revision of patent legislation in this country naturally calls for a handbook, which shall treat the subject entirely from the view of a person in the present transition state. This the authors have set themselves to do by first giving a summary in popular language of the new Act, and following it with the full text of the Act. In this later portion they interpolate the official text with explanatory notes, which should assist in making clear the difference between the present legislation and the past. Even a layman is familiar with certain provisions of the new Act, such as the reference to prior specifications, but the more subtle nuances of patent law and practice require some such guide as the authors now themselves to be. One may commend the book to those of our readers to whom patent protection is of importance.

SOUTH DEVON.—Under this title Messrs. Adam and Charles Black have issued a volume of their colour series, illustrating the topography of South Devon with reproductions of the paintings of C. E. Hannaford. The text is by Mr. Chas. R. Rowe, known to many of our readers for his journalistic connection with photography. Mr. Rowe can justly claim to know Devon as intimately as anyone, and his descriptions of incidents and places add greatly to the interest of the volume. Delightful haunts for the photographer are Dartmouth, Exmouth, Totnes, Kingsbridge and Torquay, and if Mr. Hannaford adds glamour to the colouring, Mr. Rowe no less lends romance to the travels of the tourist. "South Devon," published at 6s., is decidedly a book to draw one to the West Country on the first touch of spring.

## Dew Apparatus, &c.

the "Nulli Secundus" Anastigmat. Sold by A. E. Staley and Co., 19, Tavies Inn, Holborn Circus, London, W.C.

An anastigmat lens at the ridiculous price of 50s. for an instrument 7 inches focus is the offer which Messrs. Staley make until November 30. While we cannot explain the commercial wisdom of selling lenses at precisely half its list price, it is, nevertheless, our duty to write of the instrument as we find it. Hence we are bound to say that the "Nulli Secundus" taken for our trials from the number which happened to be in stock at the time, has been found to be an anastigmat objective of remarkably high quality. At its full aperture of  $f/6.8$  the lens covers a half-plate perfectly to the extreme corners, a test which we were able to increase in severity by raising the lens nearly level with the top of the plate; the lower part was still satisfactorily covered. The lens, it is evident, has a very flat field, and is able to cover a plate considerably larger than that for which it is listed, and this without resorting to a small diaphragm. Messrs. Staley have demonstrated its covering power by a photograph of a landscape taken on a 12 x 10 plate, and will send a bromide print from the negative for the sum of sixpence. The lens is undoubtedly capable of

very fine work over a large angle. The "Kew" tests of the lens made at the National Physical Laboratory, have shown the lens to be one of excellent quality, but as doubt has been cast upon the Kew certificate by a contemporary, we may be allowed to say that the official duplicate of the certificate sent out by Dr. Glazebrook is quite unmistakable in its report, and is, moreover, innocent of the particular inconsistencies referred to by our contemporary—that is to say, the focal length is correctly stated as 6.54 inches, or 16.60 cms., and the maximum semi-angle of field tested is plainly specified as

31.4 degrees. Our contemporary complains that in the copy of the certificate examined by them this figure is so written as to be indecipherable, ignoring the fact that this semi-angle is that subtended by the half-diagonal of the plate, that it occurs twice in the Kew report, and that if it did not occur at all is readily calculable from the focal length of the lens and the diagonal of the plate. There can thus be no doubt as to what is meant. We hold no brief to defend the National Physical Laboratory—it is well able to take care of itself—but we may refer to the matter as an instance of hypercriticism. Our contemporary admits that the Kew tests show the lens to be an excellent instrument, therefore our assurance of the definiteness of the Kew tests may well be put on record.

## Dew Materials.

"Grosvenor" (Private) Greeting Cards. Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

In the way of Xmas greeting Messrs. Houghtons offer a series of cards for the reception of photographs which should meet with undivided favour from the professional photographer inasmuch as their use (to the photographer's profit) does not involve him (the photographer) in the purchase of stock which he may not entirely dispose of. Messrs. Houghtons adopt the all-convenient idea of the private greeting card. They manufacture it in some five and twenty varieties, and put a specimen book of the cards in the photographer's hands for the sum of half-a-crown, which amount they remit on the execution of orders to the total of £2 10s. The half-crown, we should add, includes a book of order forms and counterfoils. Thus the photographer is able to let his customers see a variety of cards into which any photographs are inserted for them, while at the same time any one of a series of seasonable greetings may be selected. The cards may be ordered in lots of 12, 25, 50, and 100, and the prices for these quantities range roughly as follows:—

12	25	50	100
4/-	6/-	10/-	19/-
6/6	9/-	16/6	30/-

which are inclusive of good quality white envelopes. At these moderate prices to the customer, there is still a substantial profit to the photographer, and Messrs. Houghtons' proposition is one which we may feel certain will not be ignored. We have reason for saying that those who have tried the experiment of the specimen book have not found themselves disappointed in the results. A window card, bearing two

specimen cards and announcing that the album may be seen within, goes out with the book of specimens at the price of 2s. 6d. already mentioned.

Leto "Cream Crayon Smooth" and "Platino Matt" Gaslight Papers. Made by the Leto Photo. Materials Co., Ltd., 3, Rangoon Street, London, E.C.

In introducing two new brands of the Leto gaslight paper the makers have undoubtedly answered the demands of photographers for a paper which is not only good as regards colour of the image and gradation of the print, but is, moreover, pleasing in its surface. The "Matt smooth" paper of the same manufacture is a very satisfactory product in this latter respect, and it is characteristic of the far greater attention paid to the aesthetic effect of a photographic print that there should be a market for still two other varieties of the paper. However, the Leto Co. cannot be charged with overburdening the dealer with different brands, for the series of gaslight runs to six only in all. Of the two new products the "Cream Crayon Smooth" has a very delicate tinted surface, and is eminently suitable for development to the warm tone given with the first of the formulae recommended by the makers, namely, adurol. The warm black tone thus obtained harmonises well with the warm tint of the paper, and the result is a print of peculiarly pleasing character. The "platino matt" on the other hand best lends itself, we think, to the colder tone of the metol-hydroquinone developer with which an excellent cold black of great strength and brilliancy is produced. Opinions may differ as to the procedure we have suggested, but it will surprise us to hear either product described as other than a gaslight paper of excellent quality, giving beautiful results on direct development, and lending itself well to the hypo-alum and other methods of toning.

Xmas Calendars and Cards. Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

The mere man will be grateful to Messrs. Houghtons for producing and drawing attention to, so utilitarian a form of Christmas greeting as a wall calendar, an article which, fortunately, is none the worse for having a photograph inserted in it. It is no disparagement, but quite the contrary, to the many admirable greeting cards issued by Messrs. Houghton and others, in a state of readiness for photo-

graphic embellishment, to acknowledge that their final destiny, once they have been despatched to some uncontrolled male recipient, may be long delayed, but in the end is not infrequently—the waste-paper basket. However, it is satisfactory to know that, fortunately for the post-office, Messrs. Houghtons, and the stationery trade, such objects of solicitude are immeasurably outnumbered by the thousands (of the opposite sex) who welcome the arrival of such missives. For these, corresponding thousands must labour while yet there is time, and while yet they can obtain such excellent supports for the gems of their summer's photography. Therefore the large list (with half-tone illustrations) of the cards and calendars just issued by Messrs. Houghtons should be assured of quite a number of consultants if only from those who have perceived the wisdom of sending Xmas greetings,

which, from the fact of their including a photograph, are the most desirable of all Xmas salutations, inasmuch as they lay upon the recipient the obligation to acknowledge the greeting with something equally acceptable, such as a box of cigarettes or a bottle of writing fluid. It will be further evident from this last consideration that Messrs. Houghtons' list should be obtained quickly, and speedily made use of it. As to the cards and calendars, we must express our genuine admiration of their tasteful designs and their commendable brevity of motto. Personally we dislike to put all the fervour of the days "when we were twenty-one" on a card to be sent to, say, Jones

who owes us £5. Therefore, thanks to Messrs. Houghtons for abating the expense from gush.

We understand from Messrs. Houghtons that their list will be sent to every applicant who quotes the above sensible remarks on Xmas cards.

GREETING NEGATIVES.—Messrs. H. W. Green, of Rotherham, send us specimens of the convenient paper negatives of circle and oval design, which require only to be laid between the negative and printing paper in order to impress upon the finished photograph white letters such as seasonable mottoes as "with best wishes," &c. The negatives are sold at sixpence per packet.

THE LATE MR. W. D. VALENTINE.—The death took place at Dundee on November 7 of Mr. W. D. Valentine, of Messrs. Valentine and Son, Ltd., the well-known photographers of Dundee.

MESSRS. A. E. STALEY AND Co. ask us to announce that, owing to the great rush of orders, they will be compelled to withdraw their offer in connection with the "Nulli Secundus" lens after November 30. Foreign orders posted before that date will be executed.

SOCIETY OF ARTS.—Amongst the sessional arrangements of the Society we note that one of the ordinary meetings after Christmas will be devoted to the important subject, "Screen-Plate Processes in Colour Photography," the lecturer being Dr. C. E. Kenneth Meade.

PAPER PRINTS FROM AUTOCHROMES.—At a meeting of the Royal Photographic Society, on November 5, a demonstration of the Autochrome process was given by Messrs. Herbert Denison and F. Branson. Mr. Denison stated that he had been assured that a process for reproducing colour on paper was practically ready, its introduction being withheld until the Autochrome plate becomes more generally used. The President (Mr. Thornton), commenting on the trifling trouble, advised edging the plates with a saturated solution of solid paraffin in ether, which he had found to be a complete cure.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 15.

Sutton Photographic Club. "The Ozobrome Process." Andrew Pringle.  
Sheffield Photographic Society. "Colour Photography." Henry J. Comley.  
Stafford Photographic Society. "Rotary Carbograph Paper."  
Aberdeen Photographic Association. "Photographic Chemicals."

MONDAY, NOVEMBER 18.

Catford and Forest Hill Photographic Society. Monthly Competition. Short Address and Criticism. E. T. Holding.  
Harrow District Photographic and Scientific Society. General Meeting and Election of Committee and Officers.  
South London Photographic Society. Monthly Competition. Lantern Slides.  
Lancaster Photographic Society. "The X Rays." Dr. Gibson.  
Scarborough and District Photographic Society. "Ozobrome." A. E. King.  
Bradford Photographic Society. "Aerograph." Demonstrated. S. Hampshire.  
South Manchester Photographic Society. "Photographic Chemicals."  
Willesden Polytechnic Photographic Society. "Rotary Carbograph Paper."

TUESDAY, NOVEMBER 19.

Royal Photographic Society. "Flower Photography." E. Seymour.  
Redhill and District Camera Club. "Holiday Lectures." Members.  
Blairgowrie and District Photographic Association. Lantern Lectures by Members.  
Manchester Amateur Photographic Society. "Velox." Mr. Hadfield. "Mounting and Tinting." T. Longworth Cooper.  
Wimbledon and District Camera Club. "Lantern Slide Making." D. H. Magnus.  
Sheffield Photographic Society. "Hints to Would-be Picture Makers." H. Snowden Ward, F.R.P.S.  
Marylebone Presbyterian Photographic Society. "Rotary Carbograph Paper."  
Blyth and District Camera Club. "Advances in 'Tabloid.'"

WEDNESDAY, NOVEMBER 20.

Central Technical College Photographic Society. "The Three Z's" (Zigas, Zelvo, and Zigo). Thomas Illingworth & Co., Ltd.  
Edmonton Photographic Society. "Photographic Chemicals."  
Bristol Photographic Club. Report on the Exhibition.  
Coventry Photographic Club. Judging No. 2 Summer Competition.  
Woodford Photographic Society. "Rotary Carbograph Paper."  
North Middlesex Photographic Society. "Dark Room Manipulations." S. H. Bentley.  
South Suburban Photographic Society. "Photography at the Zoo." W. H. Wilshe.  
Borough Polytechnic Photographic Society. Lantern Slide Competition.  
Everton Camera Club. "Print and Mount Criticisms."  
Leeds Camera Club. "Florence: Its Scenery, Its Art Treasures and the Tragedy of the Renaissance." Thos. E. Green.  
Mill Camera Club. "Autochromes." Norman Fearnley.

THURSDAY, NOVEMBER 21.

Thornton Heath Photographic Society. "Rotary Carbograph Paper."  
Rodeley Farsley and Calverley District Photographic Society. "Lantern Slides." W. H. Reed.  
Liverpool Amateur Photographic Association. "Mounts and Mounting." Francis Fielding.  
Midlothian Photographic Association. "Lenses and Shutters." W. Hume and T. Haddow. "One Man Show." Alex. Allan.  
Handsworth Photographic Society. Lantern Slide Competition.  
London and Provincial Photographic Association. "Paper." E. T. Wright.  
Hull Photographic Society. "Architecture in Picardy and Provence." J. V. Saunders.  
Richmond Camera Club. "Scaloids." Johnson & Sons, Ltd.  
North London Photographic Society. "Ozobrome." E. H. Down.

## PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, the 8th inst. The following members of committee were present:—Messrs. A. Ellis, A. Mackie, S. H. Fry, D. Prodger, Lang Sims, E. Scamell, C. H. Skillman, H. C. Spink (Brighton), and H. A. Chapman, J.P. (Swansea). Mr. H. C. Spink, president, in the chair.

The Hon. Secretary reported that sixteen of those members invited to contribute to the P.P.A. Exhibition of professional work, to be held at the office of the "British Journal of Photography" in February next, had accepted, and that they would therefore have about as many pictures as they could conveniently deal with. Several of those invited had neglected to reply, although stamped addressed envelopes had been enclosed with the invitation.

At the suggestion of Mr. Lang Sims it was decided to ask the members to supply lists of the professional photographers in their neighbourhoods partly with a view to the compilation of a list of the photographers in the United Kingdom, but more particularly with the idea of making the Association known to all photographers, and giving them opportunity of becoming members of the Association.

In reference to a letter from a member of committee, making sug-

gestions with regard to members in arrears with subscriptions, the Hon. Treasurer said he considered the subscriptions were coming in very well this year. He was connected with several societies, and in that respect the P.P.A. compared very favourably with others.

With regard to a suggestion made at a former meeting that portraits be obtained of the present and past Presidents of the Association, a short discussion took place, and Mr. S. H. Fry said he would be pleased to make enlargements of the photographs of any size and in any style that might be agreed upon, and the President said he should be pleased to have made and present a suitable case and album.

A point having been raised as to the constitution of the committee, after some discussion it was agreed to recommend all alterations in the rules at the next annual general meeting.

Several other matters were dealt with of a nature undesirable to report.

## ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, November 12, the President (Mr. J. C. S. Mummery) in the chair. Forty-five members were duly elected by ballot.

Dr. Lindsay Johnson exhibited some specimens of a single lens devised by himself, and also a specimen of a dark-room clock.

A discussion on the best means of advancing the study of colour photography was then opened by Dr. C. E. Kenneth Mees, who held that the most advisable measure which the society could take was to foster the frank discussion at its meetings of processes which could not be considered to have been fully matured. He thought many methods had certain valuable features about them, and were none the less worthy of discussion from the fact that they had not reached the practical stage. Among others who took part in the discussion were Messrs. Henry J. Comley, Hector Maclean, A. J. Newton, F. T. Beeson, Oliver Dawson, H. Snowden Ward, C. P. Butler, P. Bale Ryder, and George E. Brown. It cannot be recorded, however, that any very definite suggestions were offered for the guidance of the Council of the Royal Photographic Society.

CROYDON CAMERA CLUB.—When Mr. J. M. Sellors' name is down for a demonstration, it follows as a matter of course that the subject selected will be treated exhaustively, and clearly explained. Last week Mr. Sellar selected "Kallitype," and conclusively proved that it was simple, absurdly cheap, yet capable of giving most beautiful and artistic pictures. Any tone could be obtained from true black to red on either the smoothest or roughest of papers. So far as permanence went, he could personally give no assurance, but they had it on the authority of Mr. Geo. E. Brown, F.I.C., that since the introduction of an alkaline fixing bath this desirable attribute need not be questioned. Cartridge and Whatman's drawing papers the lecturer had found suitable, and to require no sizing. He sensitized with: Ferric-oxalate, 75 gr.; silver nitrate, 30 gr.; distilled water, 1 oz. Absolute cleanliness was imperative in making up this solution. The printed image was only partially visible, and exactly resembled the initial appearance of a platinotype print. He had experienced much trouble with some published formulae for developers, but the following had worked well in his hands:—For black tones: Borax, 1 oz.; Rochelle salt,  $\frac{1}{2}$  oz.; potassium bichromate (1 per cent. solution), 7 drs.; glycerine, 1 oz.; water, 10 oz. For brown black: Borax, 1 oz.; Rochelle salt, 1 oz.; pot. bichromate solution (as above), 7 drs.; glycerine,  $\frac{1}{2}$  oz.; water, 15 oz. For very warm sepia to red: Rochelle salt,  $\frac{1}{2}$  oz.; potass. bichromate solution (as above), 2 drs.; water, 10 oz. The addition of  $\frac{1}{2}$  oz. of sodium tungstate to the last developer gave a warm colour suitable for portraiture; warmer colours were also obtained by heating the developer, and the paper used had an influence on the resulting tone. The prints were transferred from the developer straight to the fixing bath, the latter being made up as follows:—Hypo, 1 oz.; ammonia, 120 minims; water, 20 oz. In the short discussion which followed the lecture, Mr. W. H. Smith said that Kallitype certainly afforded prints of surprising beauty; there was, however, a doubt as to the form in which the silver was deposited, and this bore directly upon the matter of permanency which many thought seriously open to question. Perhaps for this reason the process had never "caught on."

## Commercial & Legal Intelligence.

**CANVASSING FRAUDS IN GLASGOW.**—A severe indictment of the canvassing swindle was delivered by the Sheriff of the Dumbarton Court last week on the occasion of the hearing of a case in which Edward Riffkin, 97, George Street, Glasgow, trading as the St. George's Art Company, sued Lawrence Watt, residing at 6, Taylor Street, Clydebank. The action was to recover 7s. 6d., being the balance of an account alleged to have been incurred by the defendant. The case of the plaintiff, or "pursuer," as he is termed in Scotland, was set forth by a partner of Mr. Riffkin, who explained that his firm did enlargements of photographs. They had an employee of the name of Muir, who left them some time ago. They got an order through Muir for the enlargement of a photograph for the defender. His firm represented that they would take a photograph and enlarge it and submit a proof. If satisfactory, they expected the order for finishing and framing. If anybody said they simply wanted an enlargement, but not the framing, they would not take the order. They asked for no deposit until they had seen the proof, but they expected to get the finishing and framing. If the proof was satisfactory, they charged for the finishing and framing, but not for the photograph. They took the sketch to defender's wife and submitted it for her inspection, and Muir came back with the order, showing that 3s. had been paid. They got an order for a certain style of frame. The price was to be 10s. 6d. After hearing the evidence from both sides, Sheriff Blair gave a verdict for the defender, with £1 costs. He said he was glad this case had been brought forward, because it gave him an opportunity of expressing his opinion of this business, which had been exposed more than once in the newspapers and elsewhere. It was quite clear that these associations were carried on for the purpose of foisting on the public enlargements and frames. He did not think it was within the power of the court or any other court to suppress them, but it was for the court to look very closely into the facts when disclosed. The *modus operandi* in this particular firm's operations had been exactly the same as in others. They went round the country; one man different on each occasion went round touting for orders. There was only one way of dealing with that man—kick him out. He induced some female—a servant or dependent who was not accustomed to business—to hand over a photograph on the representation that the enlargement of it would be a work of art and would cost her nothing. That was the first representation. Then came another man with the proof, and says: "This is what you are going to get now. We do not charge you, but you don't expect us to work for nothing; take a frame." Down comes the frame with another man, who repudiates anything said by the other man, and then sues for his money for this wretched, miserable, cheap frame, worth about 1½d. a foot. The thing was a swindle from start to finish, and the sooner the public knew it the better.

**A ROCHESTER BANKRUPTCY.**—The public examination of Arthur Fredk. Eastmead, carrying on business as a photographer at 173, High Street, Rochester, took place at the Rochester Bankruptcy Court last week. The gross liabilities were scheduled at £216 8s. 5d., and of this amount £191 10s. 11d. was unsecured. There was owing for rent £24 8s. 6d. The assets included:—Cash in hand, £1 3s. 6d.; stock-in-trade, £50; furniture, £6; and book debts, £191 10s. 11d. Debtor attributed his failure to bad trade, insufficient capital, and ill-health during the last few months. He commenced business as a photographer on the 23rd September, 1901, having then a capital of £12. His brother had originally carried on the business, and he purchased it from him for £250, payable by instalments, and of that amount he had paid £100 on account. Debtor was previously in the Navy for 22 years as a sick berth steward, and was invalided home with malarial fever from the Mediterranean, and afterwards on pension of £48 6s. per year. He had not been well since he left the service. Before taking over the business he assisted his brother. He came home really to look after him on the understanding that the house and business should be his, but, unfortunately, he did not have it in writing. With regard to his recent illness, debtor explained that he took some sulphate of zinc in mistake for Epsom salts. Debtor added

he really never had a chance to pay his brother the money for the business. First of all, his brother talked of putting him into the street; then he came back to live with him. He took the best part of the house, and agreed to pay 5s. a week rent, and that was really how the £100 was paid. This closed the examination, and the debtor was allowed to pass.

## Correspondence.

- \* \* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \* \* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### EXPOSURE OF AUTOCHROMES BY ACTINOMETER.

To the Editors.

Gentlemen,—There is one point in the report ("British Journal of Photography," November 8) of Mr. T. K. Grant's demonstration at the R.P.S. which greatly interests me. It is his experience that "where a small stop was used, such as *f*/32, he found it desirable to give a larger exposure than would be naturally proportionate to that stop. He suggested an increase over and above the time corresponding to the stop of 50 per cent."

Now, this is a similar experience to the now well-known one that Autochrome plates require a different speed value in indoor light than outdoors. But in this case it is impossible to put it down to any shortcoming of an actinometer paper testing the difference in the light. One can only conclude, as I did in my article of the previous week, that with Autochromes the usual law of intensity of light and time of exposure being interchangeable does not quite hold good, but that an allowance is necessary.

My object in writing is to ask if any readers can give their experience of the exact allowance required to be made with a stated difference of light, whether tested by an actinometer or caused by a difference of stops. I find that I shall have no difficulty in plotting out a special front dial for the Bee meter which will make the allowance both as regards light and stops, if I get data to work on.—Yours truly,

ALFRED WATKINS.

The Watkins Meter Co., Hereford.

[We believe that the apparent discrepancies as regards exposure with small stops are not peculiar to Autochromes. It may be accounted for in part by the fact that with lenses of variable thicknesses central light pencils pass through only the thickest part of the lens where a small stop is used. With a large stop the whole of the lens is utilised, including the thinner portions, which stop less light. According to Dr. Paul Kruss, a modern anastigmat stops from 19 to 3 per cent. of the light. An old lens will probably stop more, and in one composed of lenses that are appreciably thicker in the centre than at the margins we may expect variations with different stops. Such differences should be noticeable with any slow plates of small latitude.—Eds. "B.J."]

### POSTCARD PORTRAITS.

To the Editors.

Gentlemen,—Recently I selected from my stock of negatives of children some forty or fifty subjects, all of which were charming little pictures. I printed them in collodion chloride, cabinet size, or a little less, trimmed them with a very narrow white margin, and arranged them to exhibit all in one frame. Judge of my chagrin, on being greeted in the street by a lady: "Oh, Mr. Barry, I am so please you have started to do postcards of children. I will bring my three in to have a few of each done. Of course, they will be the usual price, twopence each."

Needless to say, the frame is no longer on exhibit.

Does not the incident illustrate the association of ideas and the debasing influence of environment?—Yours faithfully, W. BARRY.

The Studios, 7 and 8, Park Street, Hull.

## THREE-COLOUR CARBON PRINTS.

To the Editors.

Gentlemen,—In the interest of three-colour workers I should be obliged if you will allow me to correct a couple of misleading discrepancies in the report of my lecture and demonstration of three-colour carbon at Southampton, published in the current issue of the *J.*

I am reported to have recommended the use of a 10 per cent. solution of sodium hydrate as a means of assisting the development of carbon prints which had become partially insoluble by overexposure or otherwise. The bath I employed at that demonstration contained  $1\frac{1}{2}$  drams of sodium hydrate to 20 ounces of water. This is less than 1 per cent., but is so powerful in its action that the film can be merely dipped into it for a second, and immediately returned to the developing water, when development will proceed automatically. A 10 per cent. solution is useful as a stock, but for use a bath made of sodium hydrate 10 per cent.; stock solution, 30 minims; water, 1 ounce, will generally be found sufficiently strong, particularly if the bath is used at a temperature of 80°.

The report further states that both ammonium and potassium bichromate may be used with methylated spirit for sensitising carbon prints. For the making of a spirit sensitiser common methylated spirit is that which can be desired, but ammonium bichromate can alone be used in it. A potassium bichromate sensitiser must be made up with water only, as spirit causes the potassium salt to be immediately deposited.—I am, yours faithfully,

HENRY J. COMLEY,

Hon. Sec. of The Society of Colour Photographers.  
Turrey House, Stroud, Glos.

PORTRAITURE BY THE MERCURY-VAPOUR LAMP.—Owing to great pressure upon our space this week we are compelled to hold over, among other matter, an article on the use of the mercury-vapour lamp for portrait work in the studio. This will appear in our next issue, and will complete the series of articles on methods of artificial lighting which we have published during the present exhibition in our offices of examples of artificial light portraiture.

AN ASCENDING GELATINE MANUFACTURER.—M. Alfred Schweizer, Officer of the Legion of Honour who disappeared recently, was the "Petit Parisien" proprietor of an important gelatine factory which provided this substance to the Assistance Publique (Parisian Poor Law Administration). He appears to have speculated somewhat largely, and to have recently had heavy losses. The deficit is estimated at 200,000fr. (£28,000).

A series of four lecture-demonstrations on "The Theory of the Microscope" will be given by Mr. Conrad Beck, F.R.M.S., at the Society of Arts, John Street, Adelphi, W.C., on Monday evening, November 25, December 2, 9, and 16, at 8 p.m. The lectures, which will be illustrated by lantern slides and diagrams, judging from the syllabus, be of an extremely useful and interesting character, and should prove of great value to all interested in this branch of optics. The syllabus is as follows:—"The Microscope Constructed from Uncorrected Lenses."—Image formation by a lens, simple microscopes, three forms, investigation by a system of their defects and their cure by separated lenses, increasing distance increased, high power and large field obtained, eyepieces, positive v. negative, Ramsden circle, magnifying power, compound microscope. "The Correction of Simple Lenses."—Bad quality of images formed by simple lenses, chromatic correction, chromatic correction, spherical aberration, zonal aberration, condition and Gauss surfaces, tangent condition, equal chromatic magnification, summary of corrections, correction of eye-piece. "Influence of Diffraction."—Explanation of diffraction, slit, convergence, diffraction pattern or antipoint, its influence on telephoto images, its size, Abbé theory, Gordon's attack on Abbé theory, relation of aperture to magnifying power, oil immersion, use of and methods of reduction of size of anti-point, limits of resolution and visibility, special cases, diffraction of the eye. "Applications of Theory."—Best combination of eye-piece and objective glass, high power illumination, Gordon's oscillating screen, use of aperture, penetration for visual and photographic work, use of cover-glass, substage condensers, achromatism and aplanatism, use of condensers, angle of illuminating cone, illuminants, monochromatic light, Wright's experiments, critical illumination, possible uses.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

## PHOTOGRAPHS REGISTERED:—

- T. Upton, 24a, Southgate, Sleaford. *Two Photographs of Edmund Royds, Esq. W. Coats, Junr., 20, Prudhoe Terrace, Tynemouth. Photograph of the "Maurelanta" leaving the Tyne, October 22.*  
D. Wayland, 138, High Road, Streatham, London, S.W. *Two Photographs of Mrs. C. Booth-Clibborn.*  
W. Heine, Bushey Cottage, Park Road, Teddington. *Photograph. Chancel of Saints Peter and Paul's Church, Teddington.*

NATIONAL GALLERY PICTURES.—I should feel much obliged if you would let me know the address of a firm who would supply me with some negatives of National Gallery pictures (not copyright).—T.

We fear we cannot. Most of the firms who go to the expense of photographing in the National Gallery usually retain the negatives and the copyright to themselves. Your only course would be to approach these firms, or employ a photographer.

RICHARD MARSH.—A description appeared in our issue of September 28, 1906. You will also find a description in the catalogue of Jonathan Fallowfield, 146, Charing Cross Road, W.

MOUNTANT, ETC.—I. Last week I made up some dextrine paste, as per formula on page 994 of "Almanac" for this year. I find, on testing with litmus, that this is decidedly acid. Is this in any way likely to affect the permanency, or to cause stains on prints mounted with it? In every other respect it is satisfactory. 2. Will you also please give me the address of a firm making small glass bottles of about 3-4 oz. capacity, and where I can obtain indiarubber corks?—TONUS.

It is certainly prejudicial to prints. We should use a little solution of carbonate of soda to neutralise the dextrine mixture while fluid. 2. Poths and Co., 4 to 6, Bury Court, St. Mary Axe, E.C., from whom also you could obtain the corks.

NOVICE.—If you select any of the leading makes of ultra-rapid plates, priced at 1s. 6d. per dozen, in the quarter-plate size you will not be disappointed. We cannot say more than this.

R. L.—We should advise you to get Abney's "Instruction in Photography," or better, Valenta's "Auscopier-verfahren" (German), in which you will find the most complete instructions as to P.O.P. There is no book dealing with bromide paper in the way you desire.

W. JOHNS.—The The Tress Co., 42, Oxford Street, London, W.; J. Epstein and Co., Rupert Street, Bristol; Alfred Osmond, 105, Old Street, London, E.C.; and Birmingham Moulding Warehouse, 48, Great Hampton Street, Birmingham.

FLASH LIGHT.—I have constructed a flash lamp in which the magnesium powder is contained in a reservoir and blown through a spirit flame, as you will see by the enclosed rough sketch. It answers very well, but the flash is not quite quick enough for some purposes. Will you please give me a formula for a flash powder to use in the lamp so as to get a more instantaneous flash than with the magnesium alone?—D. CONWAY.

There is no flashlight powder suitable for use in any such contrivance as yours. Flash powders must not be used in the way you propose, but fired in the open.

AUTOCHROMES.—1. Would you mind telling me how to prepare the

permanganate and the acid, Solution C, separately? 2. Have you noticed any increase in speed of the later batches of plates?

—H. C. H.

1. C. No. 1 Solution—Water 1,000 ccs. or 35 ozs., pot. perman. 4 gms. or 60 grains. C. No. 2—Water 1,000 ccs or 35 ozs., sulphuric acid 20 ccs. or 6 drams. Mix equal parts of each for use.

2. We have not made any exact tests, but speed certainly seems to vary.

R. W. BROWN.—We can only judge by the work done, which we have seen. It is certainly equally good in the two cases.

**DAMAGED BACKGROUND.**—I have had three of my backgrounds badly mottled with the damp, the marks being about the size of a sixpence or so. They are high-priced grounds, and done, I believe, in flatted oils. My studio is large size, 36ft. by 16ft., and I have difficulty in getting it warmed. I use a large oil stove (movable), as the fireplace is at one end, with the result a fire does not spread the heat around. Can anything be done to preserve the grounds by coating them over with any preparation which would repel damp, and at the same time not affect their value in photography? I have some new grounds in, and am afraid of them starting the same; it is such a loss. I may mention the grounds are hung on frames, and always remain so. They are never rolled up at all. Any suggestion from you to remedy this evil will be gratefully received.—RETINA.

If they are done in oil we see no reason why they should become mottled with damp. But if they are in distemper it is conceivable that the size in the colour might develop mildew when exposed to continued damp, when it probably would show in spots such as you describe. The only suggestion we can make is that you keep the backgrounds dry. You cannot expect to keep a studio the size of yours either dry or warm in cold and damp weather with an oil stove. To do that properly you should have one large, or two small, slow combustion stoves, such as mentioned in an article on page 823 of the issue of November 1.

**COPYRIGHT.**—A firm of postcard publishers has, without my permission, reproduced, in postcard form, a copyright photograph of mine. Before I write them on the subject I would be glad to know what would be a reasonable sum to accept in case of settlement.—W. M.

If the card is reproduced in bromide, photogravure, or other process, justifying a 2d. card, we should say £2 2s. to £3 3s., or half the amount if the card is sold at 1d.

**FIREPROOFING FABRIC.**—Will you be kind enough to inform me, if possible, of a formula which I could use to make some linen fireproof (using it for flashlight purposes)?—J. BLAKE.

Alum, 80 ozs.; ammonium carbonate, 2½ ozs.; boric acid, 1½ ozs.; borax, 1¼ ozs.; water, 2½ quarts.

G. RAY.—You want a good deal, and to get all in one lens will cost you a pretty penny. A lens such as the new Tessar *f*/3.5, or the Holostigmat *f*/4.5, will be small enough for your half-plate camera, but perhaps not quite as rapid as the best portrait lens. We advise you to allow your dealer to supply you with the largest aperture portrait lens he can, and, to use the dark slides, have an adapter fitted to the studio camera.

A. POWELL.—We cannot give you precise figures—an electrical paper can do that—but most companies make a reduction on current used in the day before 5 p.m.

G. A. W. R. (New Zealand).—A 10 x 8 R.R. should certainly cover a 1/1 plate easily, but the definition will not be as crisp as that produced by an anastigmat. If you want great depth and sharpness you should have a shorter focus anastigmat, one of, say, 9 or 10 ins. Your requirements are inconsistent. The extra depth of the R.R. is only due to want of correction. Spherical aberration increases depth at the expense of sharpness, hence you cannot have extra depth and very crisp definition at the same time. The lenses you mention are probably all good enough.

**FILMS.**—We can understand the failure of the freshly made developer having been due possibly to the omission to shake up before use. The caustic soda and carbonate can easily accumulate at the bottom of the solution, leaving the upper portion so weak in

alkali as to render the developer inert. Metol-hydroquinone, pyro-metol is a better developer for films. It is possible the developer was unduly cold; this would account for the lack of action, though not for the fog.

L. G.—1. Certainly he has. You have no right to show the photo anywhere, or make use of it for purposes of your own. You were paid for taking it, and although the negative is yours you must do nothing with it except to the order of your customer. If you do, he can obtain an injunction in the Court of Chancery, and that would be a very costly matter to you. The only suggestion we can make is to give a long exposure. Failing that, you had better employ artificial light—magnesium or flash powder.

**PHOTOGRAPHING BANK NOTE.**—A friend of mine, who is engaged at a bank, has offered to get me a Bank of England note for £10 to photograph if I give him a dozen postcards of it. It occurred to me that if I published postcards of a thousand-pound note they would have a good sale. Will you please advise me if the publishing of the cards would be illegal, as I should not wish to get into trouble about it.—G. ANDREWS.

What you propose to do would certainly be illegal, though the copy of the note were much smaller than the original. It is illegal to copy banknotes in any form whatever, and we should advise you to abstain from doing so, either for publication or private circulation, or you will find yourself in trouble.

**UNEQUAL QUALITY OF WORK.**—About a month ago I arranged with a stationer in the town, who publishes postcards of the surrounding villages, to take a dozen views of this place, to be equal to the others which he has. When I showed him my proofs he compared them with others, and then refused to accept them, saying they were too bad for him to publish. Some of them had to admit, were not good, but others were, yet he would not have any of them, saying he wanted a dozen, or more. Can I compel him to have, and pay for, those that are good, and can I claim something for my trouble?—VILLAGE PHOTOGRAPHER.

We do not see that you can claim anything. You arranged to take a dozen views, equal to others published, and according to your account only some of them were good. Evidently the stationer wants a series of a dozen views, such as he can publish, and those you have not supplied; he is therefore not in rejecting the lot. You have not fulfilled the agreement made, and for that reason you have no claim upon him.

**IVORY and others.**—In our next.

**CINEMATOGRAPH.**—Is the effect of an unnaturally quick movement, such as a man appearing to arrive at the end of a long journey immediately after starting, caused by the operator turning the handle quicker?

No. Such effects simply mean that part of the film has been cut out owing to defects or damage, or that the series of exposures has been made on two or more films that have been afterwards joined together.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received only to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Electrical Transmission of Photographs. We publish a full account of M. Belin's method of telegraphing a photograph. The details of the method is a carbon relief. (P. 880.)

Some hints on installing the mercury-vapour lamp are contributed by Mr. G. R. Henderson, one of the exhibitors in the present collection of artificial light portraiture to be seen at our offices until November 30. (P. 822.)

Some further notes on portraiture by the enclosed arc lamp are given on page 886.

The continuation of Baron von Hübl's articles on "Artificial Lights in Photography" appears on page 885.

The Krays screen-plate process of colour-photography is reported to have been demonstrated in Berlin. (P. 894.)

Some preliminary details of the Photographic Convention at Brussels next year have been announced. (P. 887.)

We regret to record the death of Mr. Thomas Taylor, the ex-president of the Birmingham Photographic Society. (P. 884.)

Some notes on the official tests of lenses carried out by the Royal Physical Laboratory suggest the more useful character of the tests could assume from the photographer's point of view. (P. 879.)

Precaution in making test exposures of enlargements is mentioned on page 878.

The too rapid drying of an oil print during pigmentation is best avoided by selecting a thick paper or tissue and supporting it during pigmentation on a thick pad of wet blotting-paper. (P. 878.)

The coincidence method of focussing which can be tried by anyone is mentioned on page 878.

Two modifications of the focal-plane shutter are among the contents of the week.

A remarkable instance of canine sagacity. (P. 896.)

## EX CATHEDRA.

**Photographing Architectural Refinements.** The "Journal" of the Royal Institute of British Architects publishes an article by Professor Wm. H. Goodyear, M.A.,

which describes and illustrates an interesting application of photography. Most people have probably heard of what are called "refinements" in ancient Greek architecture. These are more especially associated with the Parthenon, which was most carefully and completely surveyed by the late Mr. Penrose for the purpose of analysing and recording all the various refinements that had been adopted by the ancient builders. Mr. Ruskin drew attention long ago to the presence of similar refinements in various Gothic and mediæval buildings, but it has been left to Professor Goodyear to prove their existence, for which purpose he has employed photography. The refinements employed are of many varieties, and as subtle as those of the Parthenon. Their object is not in all cases obvious, but, generally, they may be described as attempts to correct optical illusions. Thus Gothic columns and piers have been shown to possess an "entasis" similar to that used by the Ancients, while walls, piers, etc., have been found to be built intentionally non-vertical, and parallel walls have been proved to diverge vertically from one another. These points have been settled by the aid of photographs representing the building, with plumb lines suspended in suitable positions, and six full-page reproductions of the photographs are given. This opens up a new field of work for architectural photographers, and those interested in architecture may like to carry out some of Professor Goodyear's tests in other buildings. A lens free from distortion is, of course, necessary, and, unfortunately, the one used is not mentioned. Obviously such tests can only be relied on when the plumb line and the wall or pier line are at approximately the same distance from the camera.

\* \* \*

**Value of Pictures and Engravings.**

During the past year or two there has been a great slump in the picture market, particularly in the works of modern masters, while those by the old masters have realised, in some instances, extraordinarily good prices. But it would now seem that these are depreciating in value, for one day last week a painting by Hoppner was put up at an auction sale at Willis's Rooms and the highest bid for it was only 4,600 guineas, while its owners a year or two ago refused an offer of seven thousand guineas for the picture. Another painting that had cost 3,000 guineas was sold for 310 guineas. While the price of paintings has been declining, that of old engravings has been increasing. In a two days' sale last week at Sotheby's the sum of £2,806 was realised for old English and French engravings. An engraving—"Mrs. Siddons as the Tragic Muse," by F. Harward—has fetched £126 at auction. The present

seems to be the time for those who wish to realise upon really good old engravings.

#### Trial

#### Exposures for Enlargements.

It is usual when making big enlargements to first make a series of trial exposures on a slip of paper, and so obviate the risk of spoiling a large sheet. There is, however, a right way and a wrong way of making the trial, and for some reason or another nearly everyone selects the wrong way, while nearly every book on enlarging recommends it. When making a series of test exposures for contact printing there is only one simple practical method. The printing frame must be covered with a piece of card, which is slid over the frame for definite distances at fixed intervals of time. The slip of test paper is thus exposed in steps, so that if 5-second intervals are used a series of exposures in the order of 5, 10, 15, 20, and 25 seconds, etc., is secured. As a general rule a precisely similar method is adopted with enlargements, but, though this method is the only practical one available for contact printing, it is not necessarily the best, and there is a very much better one that can be just as easily applied when enlarging. The objection to the method described is that each step represents a different part of the image, and the result gives only an uncertain clue to the exposure required in the densest part unless the particular step that proves to be correctly exposed happens to include that part. Obviously the best method is to select the part that presents the greatest difficulties in the way of exposure and make a test series on that part alone. This is very easily done by cutting an aperture in a sheet of card or opaque paper and pinning this shield upon the easel in such a way that the strip of bromide paper can be slipped between easel and shield and drawn past the aperture. The light should be screened off at each movement of the slip, but this is easily done by interposing oneself between lens and easel while changing.

#### An Oil Printing Trouble.

A contemporary draws attention to a frequent cause of trouble when pigmenting in a warm room. If the temperature is much over 60 deg. F. the print dries so rapidly that it begins to take the pigment in the wrong places, and very speedily becomes too flat. This occurs more often than many suspect, and undue flatness due to this reason is often put down to something else. One remedy advised, that is to work in a cold room without any artificial heat, is unpleasant. Another remedy, to frequently re-soak the print, is also objectionable, for it is very difficult to blot

off the moisture without damaging the part finished. After each soaking the whole print has to be retouched more or less all over. Generally we have found the best procedure is to adopt an extra thick and very wet pad of blotting paper for the support, and to select thick paper for pigmenting upon. If using the Bromoil process a thick bromide paper can be used, and this holds the moisture excellently. The greater part of the trouble is, however, due to the fact that the moisture quickly runs out of the blotting-paper pad at the edges. It is, in fact, forced out more or less by the dabbing action employed in pigmenting. The best remedy would probably be the use of a very shallow tray in place of the usual sheet of glass. If the pad just fitted the tray then moisture could only be lost by evaporation at the top, which loss would be small compared to the other. Further, the pressure of the brush should tend to keep the print moist rather than to squeeze the water out at the edges of the pad. Possibly, also, something better than blotting-paper could be found for the purpose. Inventors might well turn their attention to the production of a perfect oil printing pad, that will give a firm surface, keep wet, and not suck the water out of the print.

#### Fine

#### Focussing.

A patent specification recently abstracted in our pages gave particulars of a very ingenious focussing method, which depended on the correct alignment of two reflected images. This reminds us of a little known but useful method of securing sharp focus that depends on bringing two separate images of the same object into coincidence. Take a spare lens cap and cut two segments out of the circular cover so as to leave a bar about half an inch wide across the centre. The exact width must be arranged to suit the lens. With the cap on the lens objects not in focus are seen in duplicate on the focussing screen, and if we rack in and out until the two images combine sharp focus is secured. With a large aperture lens and a clearly observable distant object it is easy to focus accurately in this way, but with near objects we require a little additional assistance in the form of a finely divided scale fixed in some convenient part of the camera to register varying degrees of extension. We have found a scale divided into twentieths of an inch a very useful adjunct to a camera for this and for other purposes. Focus on a point somewhat beyond the object and then rack out until the two images coincide. Note the extension on the scale, and then rack the camera further out so as to separate the images again. Next rack in until the two images once more coincide, and again read the scale. This reading will be different from

### THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-seventh annual issue of THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC will be published on December 2. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1908 will also consist of 25,000 copies.

Among other alterations and improvements which have been made in the forthcoming volume, the publishers beg to announce that:—

All three indexes (text, advertisement, and trade addresses) will be found AT THE END OF THE VOLUME.

The size of the volume has been appreciably reduced, without sacrificing the value and scope of the contents.

The editorial article will deal very completely with the important subject of—

SCREEN-PLATE THREE-COLOUR PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The 1908 ALMANAC will contain as frontispiece a colour print by the Autotype Co., dry-mounted by the Adhesive Dry Mounting Co., Ltd. Amongst other attractive items will be found a specimen of three-colour printing by Sanger-Shepherd Colour Printing Co. and examples of three-colour work of Hood and Co., Ltd., Middlesbrough.

Our publishers desire us again to caution our readers against postponing the booking of their copies of THE ALMANAC.

#### PUBLISHERS' NOTICE.

The publishers beg to inform agents that it will be advisable to place their orders for copies immediately, as a large proportion of the issue is already booked, and a second edition will not be printed.

ther by perhaps several divisions of the scale. Alter the extension to an intermediate point, and the focus then secured will be about as perfect as is attainable. It will be noted that this method is a refined variation of the old system of taking a mean extension between two adjustments that appear to be equally out of focus. The variation is, however, much more accurate, as we substitute well-defined degrees of sharpness for two indefinite degrees of want of sharpness. A fine focussing surface is desirable, and we invariably use one consisting of a thin film of silver iodide, as described in our issue of March 30, 1906.

### Stains in Chromium Intensification.

We frequently receive complaints of brown stains produced during the process of intensification with chromium. These stains are somewhat troublesome to remove, and sometimes they will not submit to treatment, but they are very easily avoided. One form of stain is due to development in a strong light. As developers are mostly employed in the dark, very few people seem to be aware that some of them stain most violently when used in very strong light. This is especially the case with hydroquinone, but none of the others are nearly as bad. Seeing that no light is really necessary during the intensification process, anything whatever is gained by developing in sunlight, and there is no risk of stain in soft diffused daylight, or in artificial light, provided the developer is fresh. Another source of stain is too much exposure during the washing between bleaching and development. If one film in a plate is partly covered by another the more exposed part will become a darker tint owing to the action of light on the bichromated gelatine, and this irregular action will probably be visible after development. Sometimes, however, the gelatine becomes tanned or hardened by the exposure, while at the same time the silver image becomes solarised, in which case the image refuses to re-develop. Here, again, safety lies in operating in a weak light. Another source of stain is insufficient washing between bleaching and re-development. These stains are, however, very slight and generally unnoticeable. If the image is bleached before all the hypo is washed out of the film, there is no danger of stain if the bleaching solution acts long enough, for it is a most effective hypo eliminator; but if the original image was perfectly fixed a stain of a quite fatal character may be produced. Such a stain cannot be remedied, but the others can generally be removed by putting the plate or film through the process again and allowing the bleaching solution to act for a considerable time. A very useful bleach for this purpose is one containing 10 grains bichromate in 20 minims hydrochloric acid in every ounce. This is of little use for intensification, but an excellent cleanser.

### THE GERM IDEA OF THE NEW CARBON-BROMIDE PAPER.

It is surprising how useful and really valuable photographic inventions, made years ago, lie dormant until they are unearthed, or probably re-invented, and extended on business lines by some enterprising firm, when their value becomes realised. The commercial introduction of "Carbograph," described in our issue of last week, is a case in point. The essential idea of this process was originally invented and fully described at a meeting of the Photographic Society of Great Britain (now the Royal Society) by the late Mr. Leon Warnerke more than a quarter of a century ago. It was at the May meeting of 1881 that Mr. Warnerke read a paper on his discovery of the fact that carbon-bromide of silver, after exposure to light and development, became analogous to exposed bichromated

gelatine; that is, the exposed portions are rendered insoluble in warm water.

It should be pointed out that the method of working here described differs somewhat from that of "Carbograph." Warnerke developed the silver image with alkaline pyro, instead of with ferrous oxalate developer, his aim being to obtain direct the insoluble gelatine image, which, in the case of "Carbograph," is produced indirectly through the agency of the silver image in conjunction with potassium bichromate. It is possible that other obstacles stood in the way of the commercial success of Warnerke's process, yet it can hardly be thought that the more roundabout and successful process has been adopted until after the complete trials of Warnerke's first suggestion. However, the latter was before its time, and though a good deal of interest was displayed in it, and though other experimenters have taken it up and laid it aside, it has never attained any wide recognition until the present time. Now at length, in the product of the Rotary Photographic Company photographers have at their disposal a really simple and valuable method of making carbon pictures direct or enlarged, with only the exposure to light necessary with bromide paper. It may be interesting to quote a leading article on Warnerke's discovery in our volume for 1881:—"Great stress is laid upon the applicability of the invention to pigment printing, and there is little doubt that much may be done in this direction, for by mixing such pigments as are inert on silver bromide and also on gelatine, the process becomes still more analogous to the ordinary carbon process, with the extra advantage of greatly increased sensitiveness, so that prints may be produced by artificial light, or enlargements made direct upon the tissue, without the necessity of a transparency and an enlarged negative. But here we can see some little difficulty as to its practical application, as the tissue being dark, like ordinary carbon tissue, how is the first development—that with the alkaline pyro—to be judged?" It should be remembered that at the time this was written gelatine photography was quite in its infancy, and time-development had not been thought of.

### OFFICIAL TESTS OF LENSES.

Last week, in reviewing a lens which had reached us for notice, we referred to an official copy of the certificate granted by the National Physical Laboratory. One could not discover in this—as a contemporary has done in the original—"technical slips and carelessness," but there are nevertheless one or two matters which may be referred to arising out of the tests to which a lens is submitted at the National Physical Laboratory. The first of these is the angle over which the lens is tested for astigmatism, curvature, and distortion. As reported in the certificate, this angle is limited by the size of the plate which the lens is listed to cover. Thus in the instance before us a lens of 6.54 inches focal length is listed for a 7 by 5 plate, representing a semi-angle of field of 31.4 degrees. Therefore the tests for astigmatism, etc., are made at angles from the axis increasing by 5 degree differences up to the maximum half-angle of 31.4 degrees. The measurements, we would submit, would be all the more valuable if they were carried further, inasmuch as photographers who purchase an anastigmat lens usually expect it "a double debt to pay." They anticipate using it, very probably at its full aperture, with its optical axis considerably above the centre of the plate, and they frequently design to employ it on a larger plate; in which latter case, it is true, they usually are content to use a smaller diaphragm. The inference, however, is that while it is advisable and proper to do as the National Physical Laboratory does, and indicate the point in the

tests corresponding to the full covering to the corners of the plate for which the lens is listed, it is equally important, from the practical photographer's standpoint, to describe the behaviour of the lens on a field outside these limits.

Our second point concerns the test of "Illumination of Field," or rather, the form in which the results are expressed. We read in the particular certificate before us that:—

The semi-angle of the cone, outside of which the aperture begins to be eclipsed, when the largest stop giving satisfactory definition over the whole plate ( $f/6.8$ ) is employed, is 3 degrees, covering a circle on the plate of 0.94 cm. (0.37 inches) radius.

Which is a clear statement of the fact that slight cut-off by the mounting of the lens commences at a small angle from the axis. Then we read:—

Owing to the diminution in the effective aperture due to obliquity, the illumination at the boundary of this circle will be reduced to 100 per cent. of that at the centre. At the corners of the plate, in consequence of the diminished effective aperture due to eclipse and obliquity, the illumination will be reduced to 14 per cent. of that at the centre.

The boundary referred to is presumably that of the circle of .37 inch radius, and when the illumination upon it is stated to be "reduced to 100 per cent. of that at the centre," the fact to be conveyed, we suppose, is that it is precisely equal to that at the centre, "reduced to 10 per cent." being a mathematical phrase innocent, as applied to abstract numbers, of the paradox which involves when used in reference to, say, dividends or the Bank rate. We think that the form of expressing the results could be made more intelligible to the average photographer.

Yet another point strikes us in regard to the diagrammatic representation of the lens' behaviour. The curvature of field and the astigmatic fields are shown by full and dotted black lines and in red lines, all drawn on a scale of full size. The deviations from the normal are not drawn on a magnified scale, as is more usually the case, therefore in a diagram representing the working of a very finely corrected lens the various lines are so close together that their meaning becomes confused. In the diagram before us it is next to impossible to distinguish the various curves, excepting at the few points where their divergence is greatest; hence the diagram does not convey anything like the information that would do if two different scales had been employed.

## THE ELECTRICAL TRANSMISSION OF PHOTOGRAPHS

[Our Paris correspondent's account of M. Edouard Belin's method of transmitting photographic images electrically is, we believe, the first technical description of the Berlin system to reach this country. In publishing it we would refer those who have written us as to Professor Korn's method to our issues of July 7 and 14, 1905, and of December 14, 1906, wherein are described the principles and later developments of the Korn system.—Eds. "B.J."]

THE fascinating problem of transmitting pictures by wire has occupied the minds of many photographic scientists (c.f. R. Liesegang "Die Fernsehen"), and recently general attention has been drawn to it by the remarkable results obtained by Prof. Korn, of Munich. As was intimated some months ago in our columns, a French scientist, M. Edouard Belin, of Nancy, has been also engaged with this question, and the interview and demonstration which he afforded at the Société Française de la Photographie, Paris, inspire confidence that a very considerable advance has been made. It is known to many that M. Belin has made himself expert in sensitometric problems, and it is these studies which have led him, he claims, to the solution of some of the most important problems in technical photography. Transmission of a given photograph by wire, a self-registering opacity-meter, a registering sensitometer, and last, not least, the transmission by wire of the image of any given person, object, or proof! The last problem, not to be confounded with the first, is the one M. Belin has been longest devoted to, but, having put it aside for the others, its solution is not complete. None the less, he is confident of success, and that fairly soon. The first question, which has attained a certain solution from Herr Korn, M. Belin claims to have completely solved, but in a quite different manner, and also fulfilling certain stringent conditions of which Korn's method is incapable. These are:—

1. That the image received should be of precisely the same dimensions as that transmitted: Korn's images are reduced in size.
2. That they should be reproduced, or reduced, or enlarged, if desired, but the detail should remain on the same scale as if the original size were preserved.
3. That, whatever the original, a positive or negative image can be formed at will at the receiver. The value of this for photo-mechanical processes is obvious. The nature of the original is simply telephoned to the receiving station, when adjustment is made accordingly.

4. Further, the image received shall be of the same intensity as the original, or, if desired, can be intensified or reduced. And this is obtained by no subsequent chemical treatment, but during transmission by a simple physical adjustment.

It now remains to describe the apparatus which performs the marvels. The complete model installation, containing transmitter, receiver, motor, and a resistance-line of 4,000 ohms equivalent to several hundred kilometers, is mounted on a stage about a meter square, and M. Belin kindly explained the functioning of the apparatus. The two photographs give a very good idea of its disposition.

### Telestereography.

To commence with, the method is entirely different from that of the German savant, which, as is well known, utilises the vari-

Fig. 1.

A—Ammeter. V—Voltmeter. O—Resistance coils. o—Main resistance. S—Style or point. R—Receiving cylinder. T—Transmitter.

ing electrical resistance of selenium when exposed to light. Belin calls his procedure "Telestereography," or transmission a relief to a distance, and one essential lies in the use of a carb-

print as the original transmitted, such a print being, of course, a relief in which the contours are proportional to the intensities of the image.

This print is wound on the cylinder of the transmitter T. In perfect synchronism with this revolves the cylinder of the receiver R, the synchronism being effected by the use of an alternating current in the same manner as adopted by Prof. Korn. As the cylinder of T revolves a small point or style in contact with it moves along the axis P, which is geared on to the cylinder of drum. The conditions chosen are such that the print advances linearly 1 mm. for six turns of the cylinder, from which results that detail down to  $\frac{1}{2}$  mm. is faithfully reproduced. The movements of the point or style are transmitted by an arm to a small sliding contact or roulette, working on a minute rheostat. This rheostat consists of twenty very small plates of copper separated by layers of mica and each branching off to a resist-

### The Receiving Apparatus.

The variations in the current of the circuit, proportional as they are to the intensities of the image, are registered by the extremely delicate galvanometer of Blondel, known as the oscillo-

Fig. 2.

graph. The great advantage of this instrument is its immediate response to variations of current, it being capable of following changes occurring as fast as 50,000 per second. On the mirror of the galvanometer falls a beam from a Nernst lamp, the oscilla-

- D.—Transmitting cylinder with moving point or style, acting as a sliding switch.

- E.—Minute rheostat, transforming the movements of the style into resistance-variations.
- F.—Ammeter, voltmeter, and switches.
- G.—Motor.
- H.—Lens and scale of tones through which the reflected ray passes to receiver.

and coil.<sup>1</sup> There are thus twenty variations of the intensity of the current possible. At the commencement, before the variation introduced by the cylinder, there is simply a large resistance of 4,000 ohms, the movement of the transmitting cylinder and the style then call into play the variations, always according to the contours of the carbon image, and hence in proportion to the values of light and shade. One may compare the arrangement to a delicate finger, running over the relief and transforming the variations of intensity into variations of electrical current. It will be seen that such difficulties as Korn's method has to meet, in the "chemical sluggishness of selenium," are entirely avoided in that of M. Belin, which depends on a purely physical action. Nor is it a small advantage that the carbon print is of great permanence and durability. So much for the transmitting mechanism.

(1) M. Belin explained that he had chosen a range of 1-20 as representing the possible range of contrast in photomechanical processes.

tions of the reflected ray are then proportional to the intensities of the current. Bien! Let us then follow the reflected ray.

The diagram (2) explains the disposition which enables the registration as a photograph to be effected of these electric fluctuations. An aplanatic lens  $l$  throws an image of the reflected ray from the mirror  $f_1$  on to a small hole  $f_2$ , this hole being  $\frac{1}{2}$  mm. in diameter:  $f_1$  and  $f_2$  are conjugate foci of the lens. Behind this minute hole revolves the second synchronised receiving cylinder R, on which is a photo-sensitive surface. The hole is so near the film as practically to be in contact with it, so that any diffusion of light is avoided. In other words an image of the hole is continuously printed on the film, and this means that detail is preserved to  $\frac{1}{2}$  mm. Under these conditions, there would still be no variation of the light intensity. The way this is effected—that is, the method by which the deviations of the galvanometer are converted into light intensities—is ingenious. Behind the lens (see Fig. 2) is a scale of tones, i.e.,

of densities (in the sense of Hurter and Driffield), increasing from bare glass to a certain value; in fact, an optical wedge. Various ways of producing this optical wedge may be employed: at present M. Belin uses a photographic plate specially exposed. The scale of densities increases in proportion to the mirror deviations, i.e., to the intensities of the current, and the more (or less) the reflected ray deviates, the more (or less) it is absorbed, so that the hole is illuminated by light varying in intensity with the intensities of the original image. The density-scale is mounted on a revolving axis, so that according to the direction of increase of density, relative to the mirror deviations, a positive or negative image can be obtained at will on the receiving film, fulfilling the third condition mentioned at the start.

#### Intensifying or Reducing.

Again, if instead of a scale of tones corresponding to those of the original, one of harder or softer gradation be substituted, the image may be obtained reduced or strengthened in intensity, and by purely physical means

It must be confessed that both the ingenuity and the com-

parative simplicity of the apparatus make it very promising. The results obtainable at present are very fair, and M. Belin hopes by certain slight modifications, such as a refinement of the rheostat and the cursive point, to greatly improve the rendering. He claims that in transmission of detail his apparatus is greatly superior to that of Prof. Korn, and its capacities in other directions also appear to transcend those of the selenium telegraph. In two or three weeks, with the promised aid of the State telegraph lines, he hopes to give a public demonstration of its capabilities over long distances, an event which will be awaited with much interest. M. Belin states that he can also transmit writing in relief by his instrument, and that the question of speed is one chiefly conditioned by the fineness and perfection of mechanical and electrical details. At present the transmission of 9 by 12 cms. image occupies about 30 minutes.

As to the more romantic problem of simultaneously photographing and transmitting the image of any object, scene, or person, M. Belin would only state that the idea involved was entirely different from that sketched above. His last words were: "Nous verrons!"

## PORTRAITURE WITH THE MERCURY-VAPOUR LAMP.

[In reference to the work with the mercury-vapour lamp at the exhibition of artificial light portraiture now open at our offices, the following notes sent to us by one exhibitor may be offered as a useful introduction to the installation of this particular form of illuminant.—Eds. "B.J."]

MUCH has been heard from our American cousins about the Cooper-Hewitt mercury-vapour lamp as an inimitable substitute for daylight, especially as connected with photographic portraiture. Be this as it may, photographers in this country are still very conservative in their outlook on artificial illuminants for portraiture. Doubtless, the results of artificial lighting, as exhibited by some few professional photographers, have done more than anything to allay the fears of those more intrepid than their fellows; and a commendable action seems afoot amongst better-class professionals. Still, much doubt appears prevalent as to what form of illuminant is best for the studio. It is to help those who are in doubt that the writer has formulated the following hints.

Until quite recently photographers looked upon the electric arc or the incandescent electric lamp as the ideal illuminants for portraiture. To work these systems, however successful they may have been, required an extraordinary amount of practice and skill, to say nothing of the enormous amount of patience required. The fittings, arrangement of screens, etc., also called for an unlimited amount of energy and zeal on the part of the operator, and a certain knowledge of electricity was called for in working the lamps; add to this the uncertainty of the electric arc lamp, the difficulty in starting the lamps, the flickering and unsteadiness of the light, and other minor faults which seem inseparable from the arc lamp, and sufficient reason is evident for the shyness which photographers show in adopting this form of lighting for the studio. The incandescent system is much better; but here, again, the heat thrown off by the lamps, the initial cost of apparatus, and the cost of running are grave faults, which the operator must consider. Twelve months' experience with the Cooper-Hewitt mercury-vapour lamps has shown the writer that none of the faults enumerated above can be laid at the door of the American system. For the benefit of those about to invest in some form of artificial lighting for the studio, the writer's method of working the lamps is given below.

#### The Mercury-Vapour Light.

The lamp consists of a glass tube 45in. long with a large bulb at one end, in which is secreted about one pound of mercury. The tube is exhausted to a high degree and sealed. The wires

lead the current to each electrode, one of which is at each end, the electrode at the bulb end being the mercury before mentioned. To start the lamp it is necessary to switch on the current, then pull the lamp down gently by the chain fixed at the tube-end, in order that the mercury may run from the bulb to the electrode at the other end of the tube, thus completing the circuit. Allow the tube to assume its normal position, letting it back gently, and without jerking. It will be noticed that, as soon as the stream of mercury breaks, an arc is formed. This arc induces vapour to arise from the mercury in the tube, and then causes the same to become incandescent. It will now be clear to all that, as there is no filament or solid substance to heat, there will be a more economical consumption of electricity than if such were the case.

It is here that the mercury vapour-lamp is proved to be cheaper than other electric lamps. It will now be necessary to explain how the lamps are fitted, and how they are applied to photographic portraiture.

#### Installing the Lamps.

It will be seen from Fig. 1 that the lamps are hung from the ceiling, as is the case with the ordinary pendant form of lamp. The lamps are sent out from the manufacturers all ready to be put into place. It will, however, be necessary to warn photographers about one or two points connected with the fitting of the lamps. In the first place, it is absolutely necessary that the polarity should be correct—that is, it must be impressed on the electrician who fits up the installation that the negative and positive wires must be fitted at their respective and proper ends of the lamp, otherwise the life of the lamp will be considerably curtailed. The life of a lamp is guaranteed at 1,000 hours, but the average life is from 2,000 to 3,000 hours. Another point which is of great consequence is the main wiring, which should be what is known as 22-wire. This should have a distance of not less than 2in. between positive and negative wires. This is necessary to prevent induction. It is only necessary to have this space left from the switch to the lamps. We will now deal with the all-important point—position. In this I cannot do better than describe my own studio and my method of working in it. On reference to Fig. 1 it will be seen that the lamps are

made to hang. This renders fitting extremely simple. My studio consists of two ordinary rooms with the division wall taken out. The height to the ceiling is 9ft. 6in. After several experiments and rearrangements, I have found the following to be the best position for the lamps:—Against one of the side walls I have a wooden bracket fixed at a height of 7ft. The top of the bracket stands out 18in. from the wall, and to the top of this is fixed one of the lamps. The tube is thus hanging at a height of

Fig. 1.

6ft. 6in. from the floor. The second lamp is hung from a batten fixed to the ceiling, and so fixed that it is 18in. further from the wall than is the lower lamp. On reference to Figs. 2 and 3 it will be seen that this is practically similar to the ordinary skylight arrangement. The resistances should be placed on the wall and as near to the lamps as possible. Next, I have a wooden frame

Fig. 2.

such as is used for backgrounds. This is fixed to the floor by means of screws placed through the feet into the floor. The size of this frame is 5ft. high and is 6ft. wide. On this another frame of the same size is fixed by hinges at the point indicated by the angle in the illustration. The top of this frame is fixed to the ceiling so that it may be lowered at any time. We now have a skeleton studio frame in front of the lamps, and it will

probably be found necessary to diffuse the light by placing muslin over the wooden frame. I might here mention that the ends of this framework are covered with art serge in order to prevent the light from coming through. As a diffusing medium, I have found that one thickness of the material known as lawn is just right for ordinary effects. The upper frame is covered with this material, and I think it is best fixed to the back of the frame by means of drawing-pins. The frame can then be lowered when the muslin becomes dirty, so that a fresh piece may be put on. The wood may now be stained, and the whole will present a neat appearance. A curtain is now hung from the top of the lower frame, and is found to be of value in preventing too much light from reaching the feet, whilst at other times it can be moved in order to obtain more light near the floor. The wall, being papered with a light paper immediately behind the curtain, will serve to reflect sufficient light in this direction.

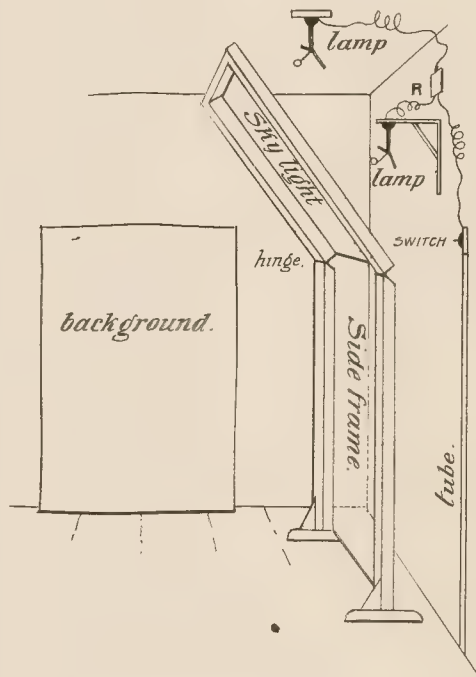

Fig. 3.

Having described the skylight, we will turn our attention to other demands.

#### Important—A Screen for the Camera.

One of the first things to be considered is the camera. It is absolutely necessary that, when using artificial light as an illuminant, the camera lens should be screened from the light itself, otherwise halation and blurring of the picture are sure to occur. To my knowledge, the best means of effecting this shading of the lens is by placing a small bellows arrangement on to the front of the camera. If this is fitted with brass telescopic rods it may be moved backwards and forwards into its correct position, which will, of course, be dependent upon the amount which is to be photographed. Having attached this bellows arrangement to the camera, the next consideration is the plate which we must use. The mercury spectrum is almost deficient in the red; it therefore follows that the blue will predominate. It is for this very reason that orthochromatic plates should not be used. It is, of course, different when dealing with arc lamps, and, indeed, any other form of light where a certain amount of

red and yellow light is present. Then an orthochromatic plate would prove to be much faster than an ordinary plate, but with the mercury-vapour lamp the exact opposite is the case.

Here I wish to say that I have made exhaustive trials of plates made by different manufacturers, and, although for ordinary purposes the plates have been of the same speed, when used with the mercury vapour-lamp each plate has required a different exposure. This, I suppose, could be explained by the scientist. The fact remains, however, that one plate is quicker than another, and I here recommend the two plates which I have found to be most satisfactory in conjunction with the Cooper-Hewitt light. In point of speed the first plate is the "Mawson," and following closely is the "Royal Standard." I have obtained excellent results on both plates.

### Reflecting Screens.

We must now consider the remaining factor of lighting. Some of the most important accessories in any studio are the screens used in obtaining various effects of light and shade, and it is in connection with these I would like to say a few words. The first I would mention is known to all photographers as the Sichel head screen. This screen is invaluable where artistic lighting is required, and, as it can easily be obtained from the dealers, I will pass on and describe the second style of screen. This screen consists of a light wooden framework about 6ft. 6in. in height, which is elongated by a brass rod, bent in the shape of three sides of a square, fixed by the ends to the top of the wooden frame, forming, as it were, a side wall and single slant roof. This frame is covered with very fine muslin, that known as butter muslin being the correct kind to use. At the bottom of this frame a spring roller is fixed, to which is attached a red blind. This blind is made to draw up to the top of the wooden frame. This completes the description of the apparatus required, and it now remains for us to put everything to its proper use.

### How to Set to Work.

Assuming that we have a sitter to photograph, we will proceed to operate in the best and most approved manner. It is here that the beginner will find most trouble, yet, if he has arranged everything as I have explained, he will be able to work correctly the first time, and he will probably be surprised at the simplicity of the method. First of all, place the sitter 4ft. from the side frame of the skylight and about 1ft. from the background end of the same so that 5ft. of the skylight are in front of the sitter. Now switch on the light, starting up the lamps very carefully. It will be seen that the light is a beautifully soft one, giving exquisitely soft shadows with beautiful sparkling lights. Proceed to focus in the ordinary way; next pose the head in the exact position required; now place the wooden screen between the skylight and the sitter, but have it closer to the skylight than to the sitter; draw up the blind until a slight shadow appears on the chin of the sitter. It will now be noticed that the head is beautifully lighted in a soft, scintillating light. Now place the plate in the camera and use

f/6 for the exposure. Expose for six seconds, and develop with the following developer:—

1. Metol .....	40 grs.
Hydroquinone .....	20 grs.
Sodium sulphite .....	400 grs.
Water up to .....	25 ozs.
2. Sodium carbonate ..	400 grs.
Water up to .....	25 ozs.

Take equal parts of each.

The resulting negative should be a distinct success. Of course, the length of exposure will depend entirely upon the particular lighting the operator may want to reproduce, but it will be found that in no case will the exposure exceed nine or ten seconds. It will also be found unnecessary to move the sitter to any great degree, as various effects of lighting can be obtained by using the two screens mentioned. Drapery can be lighted in any fashion and high-lights subdued. So soft is the light that it will be found necessary to place the reflector at least 5ft. away from the sitter; indeed, the reflector may be dispensed with altogether for ordinary lighting. It will, perhaps, be as well to mention the best form of reflector to use. That in use in my studio is one made specially from my instructions. It is simply a light wooden frame set on castors so that it can be moved easily. Fitted to this frame are two smaller frames, each of which is swung in the centre by a thumb-screw, so that they can be made to occupy any position, just as in the case of a mirror. These smaller frames are covered with light grey cloth, and when in use the reflector is brought to within 5ft. of the sitter, and the upper half is then tilted to the angle which gives the correct amount of reflected light. Being tilted in this manner, the reflector does not give false reflections in the eyes. Speaking of the eyes, it is well to mention that owing to the violet ray of the mercury-vapour lamp there is complete freedom from eye-strain. This point is in itself a sufficient recommendation for the lamp. It is a fact well known to scientists that the soreness caused to the eyes by artificial light is due to the preponderance of the red rather than to the weakness of the light as compared with daylight. The explanation of the deficiency of the red in the mercury spectrum is sufficient proof of the absence of eye-strain. Having obtained a satisfactory negative, the lamps may now be used for printing from the same, and for this purpose I have two brackets fixed under each lamp on which I place a light board. This board will hold six half-plate printing-frames, giving with the two lamps accommodation for twelve half-plate frames. The light will be found absolutely steady, and, once the correct exposure is found for any particular negative, from which, say, a platinum print is required, any number can be printed correctly by leaving the frame for the same length of time as that required in the first instance. With a negative of medium density the average exposure required for a P.O.P. print will be about ten minutes, the negative being about 6in. from the lamp. Very little heat is given off by the lamps, and even with an hour's exposure the negative would not be appreciably warmed.

GEORGE R. HENDERSON.

NEW STUDIO AT GRAHAMSTOWN.—Mr. E. J. Jeanes has opened a studio in Bathurst Street, Grahamstown, South Africa.

NELSON PHOTOGRAPHIC SOCIETY.—The second annual exhibition of this society will be held in the Stanley Street Schools, Nelson, from January 30 to February 1, 1908, the latest date for receiving entries being January 20. There will be four classes, open to all photographers, whether amateur or professional, and in each of these, as well as in those reserved for members and others residing in the district, a solid silver vase and a goblet will be placed at the disposal of the judges, Messrs. C. F. Inston and T. Lee Syms, for award. Entry forms are now ready, and may be obtained from the hon. secretary, Mr. Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

MESSRS. A. E. STALEY AND Co. have sent us a copy of the current issue of the little booklet, entitled "The Prism," published by the Bausch and Lomb Optical Company, of Rochester, New York, which deals, month by month, with the adaptation of various lenses to the photographing of Nature subjects.

DEATH OF MR. THOMAS TAYLOR.—Much regret will be felt at the announcement of the sudden death of Mr. Thomas Taylor, late president of the Birmingham Photographic Society, and a well known figure in photographic circles in the Midlands, where his home was, as well as at meetings of the Photographic Convention. Much sympathy will be felt with the widow, son, and daughter of the deceased gentleman, by all of whom much kindly hospitality was bestowed on those who had occasion to visit the Birmingham Society.

## ARTIFICIAL LIGHTS IN PHOTOGRAPHY.

## IV.

An abstract of recent papers by Baron A. von Hübl.

## The Mercury-Vapour Lamp.

This lamp usually takes the form of a glass tube, *a* (Fig. 12), of 20in. to 40in. in length, which is exhausted and has some mercury enclosed, *Q, Q*, with the electrodes cemented and fused into the glass. Various forms are given to the lamp, but they are all practically of the type shown in Fig. 12.

As the mercury vapour in the vacuum is a very bad conductor, it is necessary to "strike the arc" as with an ordinary carbon arc

Fig. 12.

lamp—that is to say, one must make contact and then separate the poles. This is done in the case of the mercury vapour lamp by tilting the lamp, so that the mercury all runs down on to the positive electrode. This should be done before the current is switched on. Then the lamp is again tilted back, so that the mercury forms a bridge to the negative electrode, and the light at once starts out. It is absolutely essential that the negative electrode be always covered with mercury; if it is not, the lamp becomes useless in a few seconds. The positive electrode, on the other hand, may be made of carbon or iron, and if large enough may be free, as shown in II. (Fig. 12). The advantage of these lamps is that they may be used in practically any position, whilst if the electrodes are small and consist of platinum wires, they must both be covered.

Practically it may be considered that to drive these lamps, two and a half volts are required for every inch of length.

The light emitted is a pale bluish-green, which, as will be seen

Fig. 13.

later, is, of course, dependent on its spectrum. The mercury vapour is extremely rich in ultra-violet rays, but in practical work the latter are of very little value. Compared with the carbon arc, the light is weak, and consequently the heat evolved is small, so that printing frames can be placed very close.

A lamp 20in. long and consuming 50 volts and 4 amperes gave the standard tint at a distance of 4in. in 70 seconds; at 8in., 1.2 seconds; so that at 4in. it is about as effective as ordinary diffused daylight.

A lamp constructed of Uviol glass showed the standard tint at a distance of 4in. in 34 seconds; on the interposition of a sheet of glass this was increased to 75 seconds. Hence the light contains 4 per cent. of ultra-violet rays, which are absorbed by the glass.

The great advantage of the mercury vapour lamp lies in the large extent of the luminous surface. As with almost all other electric lamps, the luminous area is less than 1/4 in. square; with the vapour lamp it is from 30 to 40 times as large. Obviously for the homo-

geneous illumination of surfaces it is far superior. In printing from negatives, too, this extended area enables one to dispense with a ground glass, which otherwise must be used in avoiding the prominence of retouching in the print.

The photo-chemical luminosity being practically confined to the blue and violet rays, it is obvious that in printing from yellow negatives or on carbon tissue a very long time is required.

## The Law of Exposure.

The mercury vapour lamp being practically a line or parallelogram, the laws applicable to a point of light no longer hold good; we must therefore deal with this at some length.

The curve of illumination is first plotted out for a point on a surface opposite the middle of the lamp. To find the illumination

Fig. 14.

for any other point parallel to the lamp this illumination curve must be shifted to that point. For instance, in Fig. 13, let  $L, L_1$  be the right half of the lamp; then the curve,  $C$ , applies for the point,  $P$ , on the plane,  $FF$ . For  $P_1$  and  $P_2$  this curve becomes  $C_1, C_2$ . The illumination therefore decreases from the centre to the ends of the lamp, and in ratio to the reduction of the curves. At a distance which is small in comparison to the length of the lamp and opposite its centre a point,  $P$ , receives light from almost the

whole of the surface  $e_0 = \frac{I_0}{A}$ . The illumination for the point

$P_1$  is therefore only  $e = \frac{I_0}{A} + \frac{I_0}{A} \sin \beta$ , or  $e = \frac{1}{2} e_0 (1 + \sin \beta)$ .

Fig. 15.

This formula shows the decrease of illumination from the centre to the ends of the lamp, and at  $L_1$   $\beta$  is also  $\sin \beta = 0$ ; thus  $e = \frac{1}{2} e_0$ . This spot is only half as brilliantly illuminated as the middle.

Utilising the formula,  $e = \frac{I_0}{A} \sin \beta$ , and taking into considera-

tion the distance, it is extremely easy to calculate the illumination of any point at any distance, and by increasing the latter from 4in. to 10in. to twice or four times, the illumination sinks to  $\frac{1}{4}$  and  $\frac{1}{16}$ ; not as the inverse squares,  $\frac{1}{4}$  and  $\frac{1}{16}$ . If the distance is increased from 10in. to 40in., the law of inverse squares practically applies.

Therefore for very short distances the above statement only holds good, and, as will be seen from Fig. 14, with a lamp 20in. long and 4in. distance from a plane, even illumination only extends to  $\beta = 40^\circ$ .

The illumination of a plane at right angles to the lamp axis is shown by the following: Let  $L$  (Fig. 15) be the section of the lamp, and  $F$  the plane, then the illumination at the point,  $O$ , as has been shown above, is  $e_0 = \frac{I_0}{A}$ , and for  $P e_0 \cos^2 \alpha$ . The illumination of two points on the plane,  $F$ , is as the square of the cosine of the "radiation angle," and  $OC$  is the resultant curve. Here, again,

Fig. 16.

this only applies to very short distances, for with greater distances the illumination is no longer proportional to the distance. Still the "illumination curve" is always flatter than when the light is a point, under which conditions it decreases as the third power of  $\cos \alpha$ .

### The Field of Illumination.

The illumination of a plane parallel to the lamp corresponds practically to an ellipse, the major axis of which lies in the direction of the lamp axis. Fig. 16 shows the limits of the illuminated ellipse of a 20in. lamp,  $LL$ , at a distance of 4in. The inner ellipse shows where the illumination is  $e = 0.75 e_0$ , whilst the larger one includes the area where the illumination is 50 per cent. less than under  $L$ . A sheet of collodion paper, darkened in the centre to the standard tint, showed a total area of the ellipse as 140 square inches.

### The Practical Use of the Lamp.

The light of the mercury lamp is relatively weak, and it can therefore be used at short distances—4in. to 8in.—for printing, otherwise long exposures are required. On account of the necessary proximity of the lamp, the practical field of illumination is very narrow. For larger sizes it is absolutely necessary to use a combination of several lamps. The lamps should then be mounted up parallel to one another on a plane, and the distances between them can be calculated from the law described in Fig. 4. As the "illumination curve" is somewhat flatter at right angles to the lamp axis than there stated, the distance between them,  $D$ , may be for half-tone printing 1.7  $A$ , and for fine 2  $A$ .

The lamps must always be connected up in series and on a frame to allow of the tilting for striking the arc.

The disadvantages of the mercury-vapour lamp are its fragility and the impossibility of increasing the illumination—that is, reducing the time of printing by reduction of the distance, as with other arc lamps.

## PORTRAITURE WITH THE JANDUS ENCLOSED ARC LAMP.

In an article which we published a week or two ago, our contributor, Mr. C. H. Hewitt, pointed out that while in some cases it was an advantage for the experienced electric light operator to buy his lamp and fit up his own installation, there were a great number of professional workers who wanted this done for them, and preferred to have the lamp delivered in such a form that it merely required hanging up and connecting with the cable. Messrs. Houghtons Ltd. evidently realise that this demand exists, for they are marketing the Jandus enclosed arc lamp with the addition of simple reflectors and diffuser, and judging from a series of exposures which we have had made recently, the lamp, as arranged appears to give very readily any of the effects of lighting which may be required in any portrait studio.

The lamp itself is arranged to be suspended from the roof of the studio by a steel wire cord, and is either kept in position by a balance weight or raised and lowered by means of a small winch attached to the side wall of the building, whichever method may be preferred or found most convenient in any particular instance. The lamp is of the well-known enclosed-arc type, though it has certain points of detail and design which differentiate it from other models. It gives a steady even light of great photographic value without being at all trying to the sitter's eyes. Behind the lamp, as it hangs, is placed a semi-circular reflector constructed of thin sheet iron stiffened with thin rods, this being whitened on the reflecting side with a water paint. The reflector is arranged in such a way that it cuts off all direct rays passing in the direction of the camera, and the risk of fogging the plate with stray light in the lens is thus largely obviated. This semi-circular reflector is about 5ft. from top to bottom, and 3ft. 6in. from edge to edge. In front of the lamp, that is, between the arc and the sitter, a small square screen is placed for the purpose of diffusing the direct rays of light, this screen being covered with a single thickness of tracing cloth. The lighting on the face is beautifully soft, but if at any time it should be thought desirable to dispense altogether with filtered direct light, a second frame may be slid into place, which, being opaque, will cut off all direct light, but will reflect light into the semi-circular reflector, which will, in turn, reflect it towards the sitter. The exposure, when this method is adopted, will naturally be a little longer.

As with other forms and arrangements of artificial light, some satisfactory reflecting screen must be provided for lightening the

shadows on that side of the head away from the lamp. Such reflecting screen most photographers already have at hand, so that it need not be regarded as an integral part of the lamp as supplied. A screen of good size should be used so that it may be kept fairly well away from the sitter, when many of the drawbacks attendant on the use of reflected light from a small and dead white reflector are avoided.

From a negative exposed, as described in the article, in an improvised studio at Messrs. Houghtons, Ltd., where the "Jandus" lamp has been fitted up.

Two questions will no doubt be asked at once by the photographer who contemplates purchasing a portrait lamp, first, the cost of running per hour, and, second, the length of exposure required. As to the former, the Jandus lamp is made in three sizes, either of which may be fitted up in the manner described. The lamp of which we a

now writing was of the intermediate size, and the consumption of current is as follows:—

Large size .....	15 ampères
Medium .....	12 ampères
Small size .....	10 ampères

From these figures it will be an easy matter for our readers to calculate the cost per sitter if they know their local price per unit, and the average time it takes them to make a sitting.

With the medium-size lamp a series of exposures was made on Imperial special rapid plates with a portrait lens at an aperture of  $f/5.6$ , half second, one second, and two seconds being given, and these plates developed in an ordinary pyro-soda developer all gave satisfactory, well graded negatives. As under favourable conditions an exposure of one to two seconds is a normal studio exposure, it will be seen that no difficulty occurs in making well-timed exposures which shall develop readily and give soft harmonious negatives. With nervous or restless sitters, or in the case of animals and children, where the exposures must be as short as possible, an aperture of  $f/4$  in the lens, and an ultra-rapid plate in the dark slides, will together enable exposures of less than a quarter of a second to be given, such exposures being those ordinarily known as "studio snaps."

There is no necessity for our urging on the photographer the importance of artificial light at this time of the year. Scarcely a day passes but what those workers who are not equipped with an installation realise that they are losing money either directly or indirectly on account of their reliance on daylight alone. This always uncertain factor is, of course, most fickle just now, at a time when there is a rush of sittings and orders for the approaching Christmas. A method of artificial lighting which enables ordinary fine day exposures to be given, and ordinary daylight lighting effects to be obtained, will thus be always acceptable, and such a method Messrs. Houghtons have at the photographer's disposal.

#### THE BRUSSELS (1908) MEETING OF THE PHOTOGRAPHIC CONVENTION.

It will interest habitual and prospective conventioners to know that the programme already arranged includes a reception by the Burgomaster of Brussels in the Hotel de Ville; the opening ceremony, when the presidential address will be delivered, and papers read; a conversation; a display of pictures and lantern slides of Belgian scenery by members of the Association Belge de Photographie (at whose invitation the Convention is being held in Belgium); a presidential reception by Sir Cecil and Lady Hertset in the grounds of the Jardin Zoologique at Antwerp; receptions by the Burgomasters of Ghent and Antwerp, on the occasions of the Convention visiting those cities; and the annual dinner. Arrangements are also being made to hold a trade exhibition of pictures and photographic apparatus during the meeting.

Besides the places already mentioned, excursions will be made to Malines, Louvain, and the ancient Abbey of Villiers-la-Ville. The official Convention group will be taken in front of the magnificent Palais de Justice.

For the convenience of members able to stay after the close of the meeting, cheap excursions will be obtainable to some of the most picturesque and interesting places in the country.

Special terms (about half the usual fares) have been arranged by the express and short sea routes via Dover, Calais, and Dover-Ostend. F. A. Bridge, hon. secretary, East Lodge, Daleton Lane, London, will supply all further information.

#### MR. ANDREW PRINGLE ON OZOBROME.

Those whose photographic experiences carry them back to the society life of half a score of years ago will understand that when Mr. Andrew Pringle gave a lecture demonstration—which he did on Friday, November 15, before the Sutton Photographic Club—those who were present, which included a large number of the club members, enjoyed an exposition which was broad-based upon a long and varied photographic experience, and which was explained in simple but precise terms. The lecturer stated that of all the photographic printing processes he had struck, not any was easier or more satisfactory. The possible control in vigour of a print was at least double

as much as with other printing methods in which hand-work was not the chief factor; for, in the first instance, one might modify the bromide print; and, secondly, one could, with care and certainty, alter the normal vigour of the ozobrome replica by the introduction of alum, on the one hand, or of a citrate on the other, to the ordinary sensitising solution. The chief danger in the manipulations was said to be air-bells. These, however, were easily avoided by the use of a sponge. Thus the bromide print, when immersed in water, was sponged front and back, as also was the pigmented tissue (or plaster). In the same way the transfer paper was similarly treated. Moreover, when the tissue was stripped from the bromide print, placing finger and thumb, one on each side of an edge of the tissue, the thumb was worked right round the edges, so that it wiped off any incipient air-bells, which, if present at this stage, would be found near the margin of the undeveloped tissue.

Mr. Pringle pointed out that the ozobrome process, although producing a carbon print from a bromide enlargement or contact print of the greatest perfection, was in many respects much easier to work than the direct carbon printing process. To commence with, no judgment was necessary in order to gauge the printing time, that being already settled by the bromide; furthermore, the risk of the tissue becoming injuriously affected during the drying after sensitising was eliminated. From his demonstrations and comments it is irrefutable that many professionals who may have failed at carbon printing would find that ozobrome is quite within their capacity, and that it could be successfully applied to money-making purposes. The lecturer showed a large and an unusually attractive series of prints in duplicate—i.e., the original bromide, accompanied by its carbon image, and stated that as illustrating that one could eat his cake and yet have it still, and this over and over again, some of the bromide prints, including one dating from 1886, had been bleached and redeveloped from twelve to twenty times, and yet looked as good as ever. The bromides with which Mr. Pringle demonstrated the process—one of which was a copy of the late Colonel Gale's once all popular "Sleepy Hollow"—having, after printing their images on the carbon, been washed, were redeveloped with amidol, thereby regaining their pristine vigour and colour.

The chairman—Mr. Hector Maclean—drew particular attention to the great value of ozobrome for record photography. There were, he said, no doubt tens of thousands of bromide prints in existence which were of value as records, and which, transformed into carbons, would last as long as the paper on which they were printed, for which reason not only should an ozobrome outfit be at the disposal of record societies, but amateur photographers should acquire a knowledge of this easy and interesting method of making carbon copies from their bromide prints.

#### FORTHCOMING EXHIBITIONS.

November 5 to 27.—West of England Industrial Exhibition (Photographic Section). Sec., A. D. Breeze, Great Western Chambers, 41, Union Street, Plymouth.

November 19 to 23.—Southampton Camera Club. Sec., S. G. Kimber, Oakdene, Highfield, Southampton.

November 20 to 27.—Croydon Camera Club. Sec., H. T. Dodsworth, Enmore House, Woodside Green, South Norwood.

November 25 to 28.—Lancaster Photographic Society. Sec., Walter Gunson, Manesty, Scotforth Road, Lancaster.

November 28 to December 4.—Southsea Photographic Society. Sec., Gilbert Wood, 10, Pelham Road, Southsea.

December 5 to 7.—St. George Co-operative Society Camera Club. Entries close November 25. Sec., George Anderson, 77, Brae-side Street, Glasgow.

December 5 to 7.—North London Photographic Society. Entries close November 30. Sec., C. H. Madden, 12, Dagmar Road, Stroud Green, London, N.

December 11 to 14.—Hove Camera Club. Sec., Stanley Read, 12, Old Steine, Brighton.

December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

January 30 to February 1.—Nelson Photographic Society. Entries

close January 20. Sec., Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

## Exhibitions.

### SOUTHAMPTON CAMERA CLUB.

THE seventh annual exhibition, now open at Southampton, is easily the best exhibition, from a pictorial standpoint, that the local camera club has held. Every year the three southern societies of Hove, Southsea, and Southampton combine and hold exhibitions successively at those three centres, and this year it is the turn of Southampton to lead off.

The pictures are hung in the beautiful and spacious Philharmonic Hall, in the centre of the town, and a special light installation has been arranged to show off the exhibits to the greatest possible advantage. Besides the usual classes there is a competitive class for residents in Hampshire and the Isle of Wight, which has been well supported. There is also a loan collection of representative British work and a selection of colour work, both prints and slides. Altogether we feel sure that all who have visited the Southampton exhibition, or can do so before it closes to-morrow night, will long remember it as a splendid show of pictorial and technical photography.

A casual glance round the exhibition is sufficient to show that the greatest improvement visible in the work of the year has been effected by the members of the local camera club; indeed, the standard of work compares very favourably with the strong open competitive class. Mr. S. G. Kimber shows 25 frames, "Not for Competition," and, as usual, most of his work is the perfection of pictorial architecture; but the few landscapes in his collection of exhibits fully bear comparison with anything of their class. His strongest picture is "In Westminster Abbey." Dr. Milner-White has three frames, also "Not for Competition," of which "A Stormy Day—Loch Hourn," would certainly have scored but for the condition under which it was entered. W. Martin is responsible for three non-competitive exhibits, all of interest; and Mr. W. R. Kay shows eight frames with the same reservation.

Miss E. Alder has three exhibits, of which the best is "A Doorway in Gloucester Cathedral"; Mr. A. D. R. Bacchus, one of the younger members of the club, has a "mention" in the technical class for "Viviparous Lizard," and also takes an award in the slides with a splendid series of frog studies. Mrs. T. L. Baker's two flower studies show great promise, and Mr. Baker's two river scenes are interesting. Mr. T. S. Bloom exhibits some good gum work, the best being "The Seaweed Cart"; and Mr. O. P. Butler has a good landscape, "A Welsh Mountain Pass." Mr. G. C. Chaloner's "Sand Bank—Poole Harbour," merits more than passing notice, and Mr. C. M. Cooper's pictorial work is attractive, especially "A Study of a Girl's Head in Profile," and "Portrait of a Young Lady." Mr. Cecil Daw has been awarded the silver plaque, presented by the editor of the "Amateur Photographer," for the best picture in the members' classes, and the winning print, "The Hillside," certainly deserves the high opinion the judge has formed of it. The breezy sky is as near perfection as possible, and the only fault one can find is the meagre quantity of foreground that has been retained. Mr. Daw's other exhibits show strong artistic temperament, but are far behind the successful work. Mr. R. G. Vaughton Dymock exhibits seven prints, of which "Llechryd Bridge," a delicate landscape, is easily the best. Mr. H. Essex has a strong collection of exhibits, and all his work shows careful thought, combined with good execution. "A Sunlit Glade" has earned him a rose-bowl in the print class, and a similar award goes to him for his slides, besides the silver medal presented by the editor of the "Photographic News" for the best single slide entered by a member. In addition to these material awards Mr. Essex has received three hon. mentions for his beautiful still life studies, of

which "Cloudberry" in particular attracts much attention and praise. Of three pictures by Mr. G. Fudge, "Lighting Up" and "Outward Bound" appeal to the general public, although they have not quite caught the judge's eye; but Mr. A. Gibbings has received an award and a mention for two first-class snow scenes, "Winter" and "A Wintery Gleam" respectively.

Mr. A. E. Henley is to be heartily congratulated upon being declared the champion for the year, and as he has twenty-five exhibits it can not be denied that he has worked hard for the honour. "Flaked with Sunshine," a fine architectural picture, receives an award, and Mr. Henley also takes three hon. mentions, one in each class in which he has shown his work. His chief success, however, has been in winning the special club award for the best collective exhibit by a member. In still life subjects Mr. Henley has always more than held his own, and this year's work shows that his powers in that direction have not decreased, especially noticeable being "Blackberry Blossom." In landscape and portraiture his work is not quite so successful, but fails principally only by comparison with his architecture and still life. Mr. C. D. Kay has been awarded a rose-bowl for "Betsy," an exceedingly delicate portrait in gum; but his "Portrait of Miss Dorothy Menpes," in the same process, is not far behind the winner; and a delicate architectural print, "St. Albans," has gained the same worker a "mention." Mr. A. B. Lawler shows a pleasing portrait study, whilst Miss Helen S. Morgan and E. W. Mudge both exhibit good work, with distinct promise of better things to come.

Mr. H. W. Miles is a popular exhibitor at Southampton, and this year he receives an award, and deservedly so, for "Becalmed," an excellent composition with but one fault, that the water appears to "run up-hill."

Mr. R. E. Parson is one of the club's new workers, but his name appears in the award list this year. "Beams of Light," a powerful yet simple architectural work, takes a premier award, and a "mention" is given to "A Sunlit Lane." In making these awards the judge has undoubtedly discriminated wisely, but "Cloister Shade" is little, if at all, inferior to the pictures he has noticed. Walter Playfair's "Old Mill" is a dainty piece of work, and a general favourite, but more careful mounting and finishing would improve it. Dr. Purvis and H. J. Quilter are to be commended for clear straightforward work, "The Meet" and "Bristol Cathedral" being respectively the best pictures by these workers. Mr. R. Robinson has not succeeded in catching the judge's eye this year, but his prints and slides are good examples of straight photography, and Messrs. A. Rumsey and F. Russell, who exhibit this year for the first time, also show good work; "Rushing Waters," by Mr. Rumsey, is a fine rendering of a mountain torrent.

Mr. T. E. Smith shows four frames, of which "A Rough Sea Off Jersey" is the best, the sense of movement in the waves being well rendered. Mr. G. C. Spencer has a good thing, entitled "The Glory of the Autumn Woods," and Mr. W. H. Trigg's two prints show artistic feeling in their production. Mrs. Tugwell's two studies of "Pine Trees" are pleasing, and Mrs. Weaver has obtained a mention for "Apple Blossom," a beautiful still life study. Mr. F. Watson has a strong architectural work, "Majestic in Decay," and Guy Vachell shows several interesting and attractive prints. Mr. Vachell takes an award for "Study of a Girl's Head."

Mr. T. M. Weaver is one of the club's leading pictorialists, and though he has received no award this year, "A Difficult Problem," a strong figure study, and "Saxon Font—Wells Cathedral," well bear up Mr. Weaver's reputation, as well as illustrating his versatility. Mr. Smith Whiting, as last year, is the leading natural history worker in the club, and "Black-headed Gull, Returning to Nest," which takes an award, is only one of many prints that might have gained such distinction. Whilst nothing of the technical is sacrificed to that end, Mr. Whiting succeeds in giving a certain pictorial quality to all his work.

The full list of awards is as follows:—

### OPEN CLASSES.

Class A.—Any subject. Rose Bowls: 289, "Little Paul," Mrs. G. A. Barton; 299, "Pastoral," Arthur Marshall; 304, "Strawberries," H. J. Comley; 318, "Portrait of a Lady, A. v. F.," R. Dührkoop; 336, "The Last Chapter," Miss Hilda Stevenson; 444, "Dingy London," Basil Schön; 484, "Life Story of a Kingfisher," Alfred Taylor. Hon. Mention: 237, "Kartoffelausmacher," H. Y. Simmons;

279, "Flecked with Sunlight," C. H. Hewitt; 292, "The Early Boat," A. Keith Dannat; 297, "Jeunesse," Miss Agnes B. Warburg. Class B.—Lantern Slides. Rose Bowls: 604, "Sunshine and Shadow," G. J. T. Walford; 607, "The National Gallery," V. E. Morris; 622, "Magpies," Alfred Taylor. Hon. Mentions: 616, "A Dainty Task," A. G. Thistleton; 623, "Westward Ho!" Thomas Carlyle; 637, "Early Morning Sun," W. A. Clark; 640A, "Nautilus Pompilius," Dr. G. H. Rodman.

Class C.—Open to Residents in Hampshire and Isle of Wight. Rose Bowls: 207, "The Garden of Allah," L. J. Steele; 222, "Pictures," Rev. T. A. Cooper. Hon. Mention: 202, "Yellow Plums," A. E. Henley; 219, "Xmas Eve," Basil Schön.

#### MEMBERS' CLASSES.

Champion Award for the best four pictures by a member in the club classes: 6, 64, 69, 80, A. E. Henley.

Class D.—Pictorial. The "A.P." Silver Plaque for the best picture in the members' classes: 51, "The Hillside," C. Daw. Rose Bowls: 15, "Beacalm," H. W. Miles; 35, "Betsy," C. D. Kay; 38, "A Sunlit Glade," H. Essex; 80, "Flaked with Sunshine," A. E. Henley. Hon. Mentions: 9, "Cloudberry," H. Essex; 10, "Blackberry Blossom," A. E. Henley; 43, "Study of Iris," H. Essex; 48, "St. Albans," C. D. Kay.

Class E.—Pictorial (for those who have not previously received an exhibition award.) Cream Jugs: 113, "Winter," A. Gibbings; 130, "Study of a Girl's Head," G. Vachell; 141, "Beams of Light," R. E. Parson. Hon. Mentions: 111, "A Wintry Gleam," A. Gibbings; 131, "Apple Blossom," Mrs. M. Weaver; 136, "A Sunlit Lane," R. E. Parson.

Class F.—Technical. Rose Bowl: 185, "Black-headed Gull, Returning to Nest," Smith Whiting. Hon. Mentions: 178, "Viviparous Lizard," A. D. R. Bacchus; 182, "Three Flower Studies," H. Essex.

Class G.—Lantern Slides (the "P.N. Silver Medal for best slide in the class): 649, "A Sunny Walk," H. Essex. Rose Bowl: 649, "The Set," H. Essex; 653, "Frog Swimming," A. D. R. Bacchus. Hon. Mention: 650, "Blackberry Blossoms," A. E. Henley.

#### BEDFORD CAMERA CLUB.

The Bedford Camera Club held their second annual exhibition in the Town Hall, on November 6, 7, and 8, and secured a large and representative entry. Pictures by many prominent workers, including a good sprinkling from the Royal and the Salon, appeared in the open classes—the one exception in this respect being the architectural class, in which there were curiously few entries. Competition in the members' classes was very keen, and Mr. Horsley Hinton in his adjudication specially commented on the high standard attained.

One feature worthy of consideration by other societies was a special class for scholars, which attracted an entry of 104 pictures, many of which, though small, would not have been out of place in other classes.

The exhibition was quite up to date in respect of a very strong invitation colour section. The three-colour process was represented by Messrs. Henry J. Comley, O. Bartlett, E. Fell, Dr. Phillips, the Rev. T. C. Fitzpatrick, and the Rotary and Sanger-Shepherd Companies. No fewer than 42 Autochromes were shown, these being the work of Messrs. E. Blake, J. Brown, Child-Bailey, W. Cullen, W. F. Slater, E. Fell, Dr. Phillips, and Mrs. Eve. The illumination of the transparencies was spoken of as perfect, the club being fortunate in numbering among its members the borough electrical engineer.

#### CROYDON CAMERA CLUB.

The above exhibition opened on Wednesday last, the 20th inst. This day coinciding with our going to press, we are therefore unable to consider the many exhibits individually; collectively, they undoubtedly represent a most gratifying all-round advance. We are given to understand that the actual number of entries shows an increase of nearly 50 per cent., a state of things possibly due to the offer of silver cups as awards, instead of the more hackneyed medal or plaque. The open classes fully maintain their position and importance, a landscape on linen, by Viscount Maitland, standing out from its surroundings on account of its large size and wonderful luminosity.

The members' classes, taken as a whole, are certainly far and away stronger than formerly. Messrs. H. P. C. Harpur, F. W. Wicks, J. M. Sellors, and F. J. Terry all show excellent work, as might be expected from pictorial leaders of the club; but several others are "levelling up," Mr. J. Kean being a very good instance. The three-colour and Autochrome processes are well represented by known workers, including Mr. Comley, and we are pleased to note that most successful Autochromes are exhibited by the president (Mr. A. E. Isaac) and by Messrs. W. A. Long, E. J. Platt, and Dr. Knott, members of the club. The judges are Messrs. Furley Lewis, Harold Baker, and B. Gay Wilkinson, whose list of awards we shall publish later.

The hard-worked executive evidently do not rely on "pictorialism" alone for securing patronage and £ s. d. For the admission price of 6d. each visitor is presented with a mounted platinotype print—as a souvenir, more than worth the initial expenditure. Mr. F. Gunton and Mr. W. H. Smith give "Angelus-Brinsmead" piano recitals, the latter, in conjunction with Mr. G. W. Watson, also giving side lectures on "Wireless Telegraphy" (showing a form of coherer specially designed by him for demonstration in the lantern), "Spark Photography," "X-rays," and the like. Mr. J. Bawcomb brings a battery of fine microscopes to reveal some of the wonders of the "infinitely small." Each night Mr. E. A. Salt gives a popular lecture on the "Autochrome Process," and, with Mr. Smith, portraits on panchromatic plates are taken at a prodigious rate by means of the oxy-magnesium light. Dr. Mees is down to-night (Friday) for "A Talk on What we Have Learned on Coloured Light"; to-morrow, the Rev. H. O. Fenton discourses on "The Lakes and Villages of Northern Italy"; Monday, the gallery closes early; on Tuesday Mr. Smith reverts to "Photographic Tiles"; and on the closing day, Wednesday, the 27th inst., Mr. Geo. E. Brown, the Editor of the "British Journal of Photography," brings the proceedings to a close by distributing the awards. The exhibition is held at Price's Art Galleries, 16, Park Lane, close to East Croydon Station, and is well worth a visit.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between November 4 and November 9:—

**CONTACT PRINTING.**—No. 24,312. To obtain perfect contact between an inflexible surface and glass photographic negatives. Charles Thomas Gardiner, Clarence Place, Kingsdown, Bristol.

**PHOTOGRAPHS IN WATCH CASES.**—No. 24,321. Improved method of securing photographs and the like in watch cases. James Thomas Pendlebury, 12A, Thorniley Brow, Manchester.

**MOUNTS.**—No. 24,332. Improvements in photographic mounts. Howard Marryat, 28, Hatton Garden, London.

**SHUTTERS FOR CINEMATOGRAPH PROJECTORS.**—No. 24,525. Improvements in automatic shutters for cinematograph projectors. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London.

**PRINTING FRAMES.**—No. 24,617. Improvements in pressure printing frames. James Pritchard and Harold Pritchard, 53, Chancery Lane, London.

**POLYCHROME SCREENS.**—No. 24,844. Process for manufacturing polychromatic screens for colour photography. Charles Répin, 100, Wellington Street, Glasgow.

**COLOUR SCREEN.**—No. 24,845. Improved screen for use in connection with colour photography. James Rice, Jacob John Carroll Culbert, and John Campbell, 100, Wellington Street, Glasgow.

**MOUNTING PHOTOGRAPHS.**—No. 24,876. Improvements in and relating to the mounting of photographs and the like. Thomas Edward Francis, 27, Chancery Lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FOCAL-PLANE SHUTTERS.**—No. 3,810. 1907. The invention consists in the design of a focal-plane blind shutter, such that the width of the exposure aperture can be very readily varied before, or after, setting the shutter, and will remain of constant width during the exposure; the aperture itself being made when the shutter is released by allowing the first, or lower, blind, to first travel the distance for which the exposure aperture has been adjusted, and afterwards to cause the second, or upper, blind to be automatically released and to be instantly clutched with, and follow, the first, or lower, blind. Then, when the first, or lower, blind has nearly reached the end of its course, the clutch is automatically thrown out so as to allow the second, or upper, blind to continue its journey until its lower edge overlaps the upper edge of the first, or lower, blind, thereby closing the aperture when the exposure is completed.

The operation of working the shutter is as follows:—When the blinds are to be wound up for an exposure, the head, or handle, 27, on the adjustable wheel 25, is turned until the cam projection 47 on the lower blind winding wheel 12 engages with the first bolt 35. By this means both blinds are simultaneously drawn up as the clutch roller 23, immediately it is free from control by the pin 53, clutches both winding wheels (12 and 18) together.

For time exposures, the cam projection 49 on the adjustable wheel 25 should be adjusted in such a relative position with the lower blind winding wheel 12 that, when the last named wheel rotates until the cam projection 47 thereon catches on the first bolt 35, the cam projection on the adjustable wheel 25 should be out of reach of the lip 40 on the second bolt 36. To release the shutter, the button 46 is pressed so that the first bolt 35 is moved down, releasing the lower blind winding wheel 12 and at the same time allowing the second bolt 36 to move upwards and catch the projection 48 on the upper blind winding wheel 18, thereby holding the upper blind 8. When the lower blind 7 has nearly completed its course downwards, the clutch 23 comes into contact with the pin 53, which causes it to be pushed back and releases the clutch, allowing the upper blind to follow when its winding wheel is released from the second bolt 36. When the pressure is removed from the button 46, the first bolt 35 is pushed into its

original position by its spring 38, and draws down the second bolt 36 through the medium of the arms 43 and 44 on the collar 42, thereby releasing the upper blind and allowing it to close the aperture and complete the exposure.

For instantaneous exposures, the cam projection 49, on the adjustable wheel 25, should be so adjusted that when the cam projection 47, on the lower blind winding wheel 12, is caught by the first bolt 35, the cam projection 49 comes in contact with the overlapping lip 40 of the second bolt 36, when the shutter is released, the lower blind travelling first, and immediately the cam projection 49 on

the adjustable wheel 25 strikes the lip 40 on the second bolt 26, it pushes down that bolt and allows the upper blind to follow the lower blind, and when the lower blind has nearly finished its journey, the clutch is thrown out, leaving the upper blind free to finish its course.

When it is desired to focus an object, the wing nut 28 of the upper blind winding wheel 18 is turned until the cam projection 48 thereon is caught by the pawl 51. To release this blind, all that is necessary is to turn the head or handle 27 of the adjustable wheel 25 when setting the shutter, and by so doing the pin 52, projecting from the clutch ring 21, pushes or turns the pawl 50 and removes the catch or tooth 51 from the cam projection 48 on the upper blind winding wheel 18, and releases that blind, thus closing the aperture before the clutch 23 comes into action. John Stuart, 3, North Side, Clapham Common; and Alfred Woods, 5, Richmond Park Road, Kingston-on-Thames.

**FOCAL-PLANE SHUTTERS.**—No. 7,235. 1905. The invention relates to focal-plane shutters, the aperture of which is adjustable. It consists in imparting the necessary stiffness of the blind by providing its lateral edges with flexible and light metallic bands or by reinforcing its tissue.

The shutter is formed by two blinds, 1 and 2, leaving an adjustable slot 3 between their ends. The lower blind is wound on a lower roller 4, actuated by a spiral spring, tending to wind the said blind 1.

The upper blind 2 is adapted to be wound on an open roller 5. The latter is hollow, and provided with a slot 6, through which pass two bands 7, the ends of which are attached to the lower blind 1, the bands being rolled on rollers 8, concentrically arranged inside the roller 5. The rollers 8 may be actuated from outside by means of a button 9.

By turning the cylinder 8, whilst the cylinder 5 remains stationary, the opening of the slot 3 may be adjusted, and an index-finger secured to the button 9, and, movable over a graduated arc, may

indicate the degree of opening of slot 3. The opening being adjusted, the bands are wound together on the roller 5. In order that, when the slot is adjusted, the bands shall not take along with them the blind 2, the latter must possess a certain rigidity, which is also indispensable for ensuring a good guide for this blind when the device is released. This rigidity is obtained either by providing the lateral edges of the blind 2 with flexible metallic bands or by reinforcing its tissue.

When the opening of the slot 3 is adjusted, the shutter is set by operating the button 10 of the upper roller 5, so as to put the spring of the lower roller 4 under tension through the intermediate of the blinds 1 and 2. The slot 3 is in this way raised so as to be entirely cut off the focal plane. When the upper roller is released by means of mechanism, such as used with instantaneous phot-

graphic apparatus, the spring of the lower cylinder is relaxed and draws the blinds with the slot 3 between them from the upper roller 5 on to the lower roller 4. Félicien Blanpain, 11, Rue Bunionceau, Brussels, Belgium.

The following Complete Specification is open to public inspection before acceptance, under the Patents Act, 1901:—

CINEMATOGRAPHS.—No. 15,902. Cinematographs and like apparatus. Mallet.

## New Books.

**COLOURING LANTERN SLIDES.**—The "Photo-Miniature" for November, 1907 (No. 83), is largely devoted to methods of colouring lantern slides, and contains instructive chapters on the use of oil and water-colours for this purpose. We read that the first wave of interest in the Lumière Autochrome process is about to sweep over America. Its point of origin is the enthusiasm of Mr. Alfred Streglitz, who, as we have already noted, has returned to the States laden with the spoils of his European labours in the process. Our miniature contemporary, as brightly produced as ever, is obtainable in this country from Messrs. Dawbarn and Ward, price 6d.

A WALL CALENDAR, with a tear-off page for every three days, has been issued for 1908 by W. Knapp, Halle a/S, at the price of two marks. It is handsomely produced on art paper, and on each page bears a reproduction, finely printed in half-tone, of an example of pictorial photography. In addition, the "Abreisskalender" contains numerous hints on practical work, presumably offered for perusal should the pictorial efforts pall. The calendar is certainly a wonderfully fine production at 2s.

## New Apparatus, &c.

Enlarging Cameras, Lanterns, and Illuminating Chambers. Made by J. Lancaster and Son, Ltd., Broad Street, Birmingham.

In this model de luxe of their enlarging lantern the makers evince the greatest care in providing for the amateur or professional user all the necessary adjustments for certainly and rapidly producing enlargements or enlarged negatives. The lantern, as will be seen from the figure, is first of all adjustable behind the condenser by winch screw, and the exact position therefore for the most even

lighting is thus obtained to a nicety. But the portion of the apparatus which will appeal most strongly to enlargers of all classes is that of the negative carrier. This latter is removable from the lantern stage, and is taken in and out in a moment. The negative is held in a revolving carrier, which, as a whole, can be moved up and down independently of its rotatory movement. The negative can thus be adjusted on the enlarging easel most quickly and accurately, and any defects in regard to the position of the picture on the plate may be corrected in the enlargement. Further than this the

carrier, as a whole, may be drawn out of the upright position in order to correct converging lines due to the camera having been tilted up or down at the time the exposure was taken. These three adjustments are all made from the outside of the lantern by screws which are close to one another, and all three of them may be done in a few seconds, whilst the image is visible upon the easel. The apparatus

is made throughout in oak, and in the three sizes in which it is obtainable—namely,  $\frac{1}{4}$ -plate,  $5 \times 4$ , and  $\frac{1}{2}$ -plate—costs as follows:  $\frac{1}{4}$ -plate, £5;  $\frac{1}{2}$ -plate, £8, without objective. With objective,  $\frac{1}{4}$ -plate, £6;  $\frac{1}{2}$ -plate, £9 10s.

In a new pattern of apparatus, named the "No. 2 Amateurs' Enlarger," the makers have very conveniently placed all the adjusting screws at the back of the apparatus, so that the worker may focus and arrange the size of his enlarged picture whilst viewing the image on the screen. In addition to this, the negative carrier is so arranged as to raise or lower the negative and to tilt it out of the position of perpendicularity to the axis of the lens in order to remedy any defects of position and distortion when making the enlargement. This adjustment again is controllable from the back portion of the apparatus. A silvered mirror is also provided, so that the instrument has only to be placed level out of a window or any other position where it will get clear light from the sky, and the even illumination of the negative follows. Well made in polished wood and folding to convenient proportions, the apparatus costs 30s. and upwards.

In the new model of the "Ellipsoid" enlarging lamp, Messrs. Lancaster employ an opal reflector of elliptical shape, which provides a very even and brilliant illumination from a pair of inverted incan-

descent burners. Moreover, the lamp is provided with an adjustable reflector, which, within certain limits, will be of assistance in helping a negative by concentrating the light more or less upon one part of it. The lamp is obtainable to fit purchaser's own camera, or can be obtained complete, as shown in the figure, with tube extension

and iris mount for the instant adjustment of the user's own lens. Moreover, the lamp can be arranged to take an acetylene burner or an "Osram" electric lamp, which Messrs. Lancaster, we are pleased to find, recommend in preference to any others.

The "Sunlight" enlarging chamber is a new piece of apparatus, in which two inverted burners are employed some distance behind the ground glass and in front of a reflector placed at such an angle that the worker practically has as the source of light a rectangular area of four incandescent mantles. The reflector is of silvered copper, and the apparatus, which is stocked in all sizes up to whole-plate, and is obtainable in the still larger sizes, provides a most efficient means of illumination for negatives to be enlarged or for the making of lantern slides by reduction.

In addition to the inverted pattern, Messrs. Lancaster have produced one in which the ordinary vertical burners are used backed by a reflector of zigzag form, which again provides a very even and powerful illumination.

## New Materials.

"Rytol" Universal "Tabloid" Developer. Made by Burroughs Wellcome and Co., London.

In this new preparation Messrs. Burroughs Wellcome offer a developer suitable for plates, bromide and gaslight papers, and lantern-slides, and free from the stigma of affecting the skin, as does metol or its compound, metol-hydroquinone. Our short experience of Rytol certainly predisposes us in its favour. We found it an excellent reagent for gaslight prints, capable of being used repeatedly, and giving a fine black colour on the Barnet new glossy paper. Rytol, too, is prepared in more concentrated form than many "tabloid" developers, and will therefore be found a most economical developer.

"Oyster Shell" Glossy Gaslight Paper. Made by Elliott and Sons, Ltd., Barnet, Herts.

When in the early part of the year we were able to speak in praise of a new brand of gaslight paper placed on the market by the Barnet manufacturers, under the title "Oyster Shell," we alluded to the appositeness of the name in reference to the characteristic delicacy of the surface of the paper; since which time our judgment has been confirmed in the widespread adoption of the paper. Therefore it is well at once to stamp Messrs. Elliott's new paper as one in no way competing with, or supplanting, its predecessor as regards surface quality. Though it bears the same title, "Oyster-shell," it has a fully glossy surface, whilst the other paper is a half matt. In other respects the new paper, according to our trials of it, is worthy of whatever good things we said of its antecedent. It develops to a fine black colour—we used the new "Rytol" tabloids which happened to be at hand—with a fine range of details from the shadows of an archway to the high-lights of a sunlit pathway, both of which occurred in the negative selected for our prints. Glossy "Oyster-shell," which is sold at the standard prices, certainly deserves the approbation of the discriminating worker.

Silketeen Lantern Slide Binders. Sold by W. Tylar, 41, High Street, Aston, Birmingham.

Mr. Tylar sends us a sample box of a new form of lantern slide binder, which he is placing on the market under the name of "Silketeen." Whilst of more durable substance than the ordinary paper form, the "Silketeen" binder possesses great pliability, and adheres to the glass rapidly and easily, though perhaps its chief advantage lies in the fact that, being of a pale pink colour and fine smooth surface, the title of the slide can be easily written on it with ordinary pen and ink. These binders may be obtained either in lengths sufficient to go round a slide, or cut in short strips of sufficient length for one side only, the price of both kinds being 1s. per box, 1s. 1d. post free.

WELLINGTON XMAS POSTCARDS.—Messrs. Wellington and Ward send us examples of the Christmas greeting postcards which they have issued in all the brands of their printing papers—viz., Bromide,

S.C.P., and P.O.P. in each case of the matt, glossy and "carbon" varieties. There are six different designs in all, and these are assorted in the packets, or, if specially desired, packets can be supplied containing one, two, or three designs, as the case may be.

## CATALOGUES AND TRADE NOTICES.

CARBGRAPH.—A convenient booklet of the instructions and formulae needed for the ozobrome process has been issued by the Rotary Photographic Co., and gives in convenient form the full instructions published in our issue of last week.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, NOVEMBER 23.

Aberdeen Photo Art Club. "Time Development." Kodak Co.

MONDAY, NOVEMBER 25.

Bradford Photographic Society. "Photographic Opportunities, on Holiday or Otherwise." A. Bracewell.  
Scarborough and District Photographic Society. "Marine Life at Scarborough." W. J. Clarke, F.Z.S.  
Oxford and Forest Hill Photographic Society. Jumble Sale.  
Kiddminster and District Photographic Society. "Hints to Beginners." H. W. West.  
Gravesend and District Photographic Society. Members' Lantern Evening.  
Halifax Photographic Society. "Rotary Carbograph Paper."

TUESDAY, NOVEMBER 26.

Royal Photographic Society. "A First Lesson in Photo-micrography." Martin-Duncan, F.R.P.S.  
Keighley and District Photographic Society. Siena, San Gimignano, and Other Medieval Cities of Tuscany." Thos. E. Green.  
Epsom and District Literary and Scientific Society. "Exposure and Development." Mr. Schafer.  
Manchester Amateur Photographic Society. "Ilford Lantern Plates." Mr. Brooker.  
Wallington Camera Club. General Meeting.  
Leeds Photographic Society. "Vesuvius and its Eruptions." Dr. Temper Anderson.  
Guiseley and District Photographic Society. "Enlarged Negatives on 'Rotary' Negative Paper."

WEDNESDAY, NOVEMBER 27.

Coventry Photographic Club. "Fruit and Flower Photography." E. Seymour.  
North Middlesex Photographic Society. "Autochrome Colour Photography." A. J. Woolway.  
South Suburban Photographic Society. "Recent Advances in Tabloids." E. C. Price.  
Central Technical College Photographic Society. "Colour Photography." S. W. de W. Abney, K.C.B., D.C.L., D.Sc., F.R.S.  
Dukinfield Photographic Society. "Photographic Chemicals." Everton Camera Club. "Flower Studies." J. Hawkins.  
Leeds Camera Club. "Rotary Carbograph Paper." Robert Gracie.  
Borough Polytechnic Photographic Society. "The Romantic in Landscape." F. C. Tilney.  
Worthing Camera Club. "Oil Printing." G. E. H. Rawlins.

THURSDAY, NOVEMBER 28.

North London Photographic Society. "Artistic Portraiture." C. Wille.  
Richmond Camera Club. "Lantern Slide Making." J. D. Gibson.  
Hull Photographic Society. "Norwegian Notes." E. L. Davis.  
London and Provincial Photographic Association. Open Night.  
Handsworth Photographic Society. Exhibition of Competition Slides.  
Liverpool Amateur Photographic Association. "Mountains and Valleys Switzerland." J. L. Robinson.  
Chelsea and District Photographic Society. "Pictorial Composition." A. C. Mountfort.  
Rugby Photographic Society. "Flower Photography." E. Seymour.  
Longton and District Photographic Society. "A.P. Prize Slides."  
Queen's Park Amateur Photographic Association. "Mounting and Framing." Pudsey and District Photographic Society. "Enlarged Negatives on 'Rotary' Negative Paper." Robert Gracie.  
Blenheim Club. "Russia: Her Peasantry and Poison." H. P. Kennard, M.I.  
L.C.C. School of Photo-Engraving and Lithography. "Half-tone Screen Negative Making by Dry Plates." A. E. Dent.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 19, Mr. W. T. P. Cunningham in the chair.  
A paper on "Floral Photography" was read by Mr. E. Seymour.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held November 14, 1907, Mr. Terry in the chair. Mr. A. W. M.

Dickens demonstrated "Scaloids," and his demonstration took the form of developing an Autochrome plate by the aid of the reagents as put up and sold by Messrs. Johnson and Sons. In these reagents the alcohol in Solution A is not used, its place being taken by a scaloid or pellet of pure pyro, hence one of the causes of frilling is eliminated. The reagents, as put up, are part in strong solutions and part in "scaloids," and the full set can be got ready in something under three minutes. A hardening bath was included in the set, consisting of chrome alum. Thirty seconds was the time mentioned for this bath to act—in the dark. In place of the hot wax for edging the plates prior to development, a new compound was now put up which answered perfectly, although it only needed putting on the edge of the plate with a linen handkerchief or duster: its appearance bringing strongly to mind the encaustic paste of olden days. In place of daylight after the reversal and prior to the second development, Mr. Dickens preferred to use 3in. or 4in. of magnesium ribbon. The plate experimented with developed up perfectly without the least sign of frill. Many specimens upon Autochrome plates were shown, and the one developed was dried and finally varnished before the meeting closed. Mr. Dickens further said that he thought one cause of frilling was the use for the washings of water which was colder than the developing solutions. Again, amidol could be used for the first developer, and this again tended to check frilling. When this was used, however, the time should be extended to three minutes. Autochrome plates could be reduced when needed by either the Howard-Farmer reducer or persulphate after fixing, the use of these in no way interfering with the colours. After intensification, the lecturer said, the washing should extend to two or three minutes, since any traces of citric acid left in the plate would tend, when in the clearing bath, to form a reversing bath. When fixed and washed the film could be—and he thought should be—blotted off with fluffless blotting-paper, as this gave quicker drying. Mr. Rapson said the time of preparing for work was a great consideration, his first set of solutions taking just 14 hours to prepare. Mr. Dickens remarked that, with the exception of the pyro and re-developer, the solutions could, if need be, be used more than once. Mr. Dickens then toned a bromide print by the aid of the sepia-toning scaloids, and said that when a good sepia was required it was necessary to develop the print well. Fresh sulphide should be used, the stale variety being the cause of yellow-brown prints.

## Commercial & Legal Intelligence.

**RECEIVING ORDER.**—Friday's "London Gazette" contains a notice to the effect that on the debtor's petition a receiving order was made on November 12 in respect to George Gibson (trading as late A. and G. Taylor), 23, Clarence Road, St. Philips, Bristol, Photographer.

**EDITOR WHO BECAME PHOTOGRAPHER.**—At a sitting of the Canterbury Bankruptcy Court last week, John Harry Gibson, of 16, Snar-gate Street, Dover, photographer, attended for his public examination. The liabilities amounted to £252 14s. 7d., and the net assets to £4 14s. 1d. Under examination by the Official Receiver, the debtor stated that formerly he was engaged on a Dover newspaper. He was in the office for many years, and for about eighteen months he was in charge, acting as editor and manager. He was in the office for eight or nine years before that. His salary as editor was £2 a week, and he had the benefit of the house. It was a limited liability company. In 1903 he relinquished that position, and for a short time was doing nothing. Then he commenced business on his own account as a photographer. For many years he had done amateur photography, and he entered into the business professionally because he thought as illustrations were coming into vogue in connection with newspapers he could turn it to some account. He started with a borrowed capital of £25, and at that time (1903) he had other liabilities up to the extent of about £100. Some of these had accrued while he was on the newspaper. The business had not

paid from the commencement. In 1905 he borrowed a further sum of £37. The rent of his premises was £40 and the rates and taxes came to from £16 to £18. He had a boy to assist him, and his daughter also helped him in the business. He estimated his turnover at about £250 a year. The reason he continued the business notwithstanding that it did not pay was because, like so many other people, he had been hoping for better times. He did not expect the business to pay the first year, but he thought it would the second or third year. Just prior to the Receiving Order a distress was levied upon his effects by the landlord. The examination was closed.

**UNACKNOWLEDGED PHOTOGRAPHS.**—In the Penzance County Court last week Messrs. Gibson and Sons, photographers, Penzance, brought an action against Mr. Uren, the author, and the publishers of a book entitled "Scilly and the Scillonians." The claim was as follows:—Contract price of sixty photographs supplied to defendants for reproduction in the book, on condition that the words "Gibson and Sons, Penzance," appeared beneath each reproduction, £15; damages for breach of the said condition, £35; making a total of £50. Plaintiffs also claimed an injunction to restrain defendants from producing the photographs in any future edition, or editions, of the book, unless in accordance with the condition. Mr. Edward Boase, representing plaintiffs, said Mr. J. B. Cornish appeared for defendants. They had agreed to ask his Honour to grant the injunction, and Mr. Cornish had consented to judgment against defendants for £40 and costs. His Honour made an order accordingly. Mr. Cornish said it was understood that this settlement covered all claims, even if they were not specifically mentioned. The matter was the result of an unfortunate misunderstanding.

**AN OLD OFFENDER.**—At Aberdeen last week, before Sheriff Begg, James Wilson (elsewhere described as "Nelson"), from prison, was charged with four acts of fraud in obtaining money from various persons in the Newhills district by falsely pretending that he would supply photographs at a cheap rate, and, having obtained part of the payment in advance, failed to fulfil his promise to take and supply the photographs as promised. The charges were that he had pretended to Robert M'Killigan, on July 26, that if M'Killigan would give him an order for twelve postcard photographs of himself and his family, accused would return on July 29 with his camera and take the photographs, and supply six of him and six of his two daughters for 2s. 3d., and thus induced M'Killigan to hand over 2s. 3d. without supplying the photographs or intending to supply them; that accused pretended to Duncan Thompson, on August 15, that he (accused) was a photographer carrying on business at Aberdeen, Edinburgh, Glasgow, and Dundee, and induced Thomson to pay him 2s. in advance to take a photograph of him and his wife and family on August 19, when he returned, the price to be 3s.; and that accused on the same day and at the same place pretended to Mortimer Thomson that if he (accused) received an order for a dozen photographs of Thomson for 2s., he would return to take the photographs on condition that 1s. of the price was paid in advance, and he thus defrauded Thomson.

Accused pleaded guilty, and said he had been promised the loan of a camera to take the photographs but did not get it. He had been in prison for a similar offence in a different county, and would like, if the Sheriff could impose, a limited penalty.

The Procurator-Fiscal Depute said accused had been sentenced to thirty days' imprisonment at Stonehaven for a similar fraud. Then, however, there were a good many other charges against the accused—twenty-five in all. The Sheriff sentenced the accused to twenty days' imprisonment.

**BRITISH MUTOSCOPE COMPANY.**—In the King's Bench Division, on Tuesday, before Mr. Justice Parker, a petition was presented by Linotype and Machinery, Ltd., for an order for the winding up of the British Mutoscope and Biograph Company, Ltd. Mr. Clauson, for the petitioners, said his clients were creditors for £606, and the usual order was asked for. Mr. Grover, for the Mutoscope Company, offered no objection, and his Lordship made the order.

**BIRMINGHAM PHOTOGRAPHER ROBBED.**—At the Birmingham Police Court last week, Albert Barrows, of Small Heath, was charged with smashing the window of a shop belonging to Mr. Baker, photographer, and jeweller, of Deritend, Birmingham, and stealing a quantity of

jewellery. The prisoner was committed for trial at the Assizes, bail being allowed.

**PHOTOGRAPHER CHARGED WITH THEFT.**—At the West London Police Court last week Austin Campbell was charged with stealing cameras by means of a trick from Messrs. W. B. Fielding, of Fulham Road, Joseph Wilson, of Chiswick, and Hardcastle, Ltd., of Brighton. In each case the prisoner had obtained the camera on approval and absconded with it. Campbell pleaded guilty, and the magistrate sentenced him to six months' hard labour.

## News and Notes.

**ENLARGEMENT FRAMES.**—Messrs. J. Epstein and Co., whose enterprise in the manufacture of picture frames is doubtless well known to the majority of our readers, are now going "one better" than heretofore, and are offering 20 x 16 enlargement frames, 3 inches wide, complete with glass and backboards, for the remarkably low price of 21s. per dozen. Such an offer should be of special interest to our professional readers at this season of the year, when orders for enlarged photographs as Christmas presents are usually extremely numerous, and such unobtrusive frames as those above described would be suitable for enlargements by practically any photographic process. Further particulars may be obtained from our advertisement pages, or from Messrs. Epstein and Co., Rupert Street, Bristol.

**A SHIPLEY PHOTOGRAPHER'S WILL.**—Mr. Stephen Stansfield, of Westcliffe Road, Shipley, Yorkshire, photographer, who died on October 7 last, left estate valued at £1,005 8s. 5d. gross, with net personality £690 14s., and probate of his will has been granted to his widow, Mrs. Annie Stansfield, of 18, Westcliffe Road, Shipley, and power is reserved to grant probate also to his daughter, Miss Elizabeth Stansfield.

**PHOTO-PENDANTS.**—Mr. F. Helmrich, lately trading at 158, Aldersgate Street, has joined the firm of Alfred J. Nathan and Co., at 17, Farringdon Avenue, where he is starting a special department for his well-known lines in photo-pendants, frames, miniature rims. A sample dozen of pendants in rolled gold,  $\frac{3}{4}$ -inch,  $\frac{7}{8}$ -inch, 1-inch, and 1 $\frac{1}{2}$ -inch, is offered at 9s. 6d.

**THE KRAYN SCREEN-PLATE COLOUR PROCESS.**—We read that a demonstration of the process has been given in Berlin on Friday last, November 15. It is likely that more will be heard before long of the process in this country. It will be remembered that the filter screen for the Krayn plate is prepared by cutting a section of coloured layers of celluloid, dyed to the suitable blue, red, and green colours.

**THE BIRMINGHAM EXHIBITION.**—The last day for entries is February 8, 1908 (February 1 from abroad); for pictures, February 19 (February 1 from abroad). Full particulars from M. Lewis Lloyd, Church Road, Moseley, Birmingham.

**THE STAFF OF SPEAIGHT, LTD.,** photographers, of Bond Street, have recently given a sign of the mutual consideration shown by them for their firm, and vice-versa, by their response to the firm's offer of a prize for the best photographs taken during the past holiday season. As a result, fifty photographs, representing about a dozen of the staff, are now brought together in a gallery at the Bond Street establishment. Among them is some most creditable work, the best of which was judged by Mr. Snowden Ward to be Nos. 21 and 22, "Monday" and "Now the Day is Over," by Mr. F. Smart. Mr. Smart has six prints, each with some claim to notice on pictorial grounds, and meriting our encouraging him to more ambitious work. Mr. Snowden Ward, in making the award, added a second prize, which he gave to "The Old Mill by Night," by Mr. A. E. Fowles. All the prints interested us from the evidence they gave of the aim on the part of Messrs. Speaight's assistants to take pains in their own amateur work. While all the photographs are undoubtedly the work of young workers, they are, in almost every instance, of a kind which exhibits more than the ordinary care taken by the amateur beginner. Mr. F. Bianchi shows in No. 2 a sense of the beauty of sunshine on a river backwater. No. 4, "A Wet Day," by Mr. F. Fraser, is not at all a bad rendering of the subject. Miss B. Meakin, in Nos. 6 and 7,

representing the launch of a lifeboat and an approaching train, is successful in getting the sensation of effort and excitement into the one and movement into the other. The figures are well placed in the latter. Mr. W. S. Smith's photographs are hardly equal in quality. His view of Swanage Bay is the best. Miss I. Shepherd must persevere. Mr. W. C. Robinson has a very good bit of woodland from Wimbledon Common (No. 28). Miss E. A. Sivelle is successful in her choice of open scenery, of which No. 32 "St. Lawrence's Valley, Jersey," is the best. The work of Miss M. E. Hider is clean, good photography. Mr. C. G. Rosher exhibits a curious preference for long narrow prints, either horizontal or vertical, but he shows that he recognises the subjects suitable for one or the other. The light bluff border to No. 45 should be a mere line, and the whole effect would then be excellent.

## Correspondence.

\*.\* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\*.\* *We do not undertake responsibility for the opinions expressed by our correspondents.*

### SECTION-CUT HALF-TONE SCREENS.

To the Editors.

Gentlemen,—The description under this head has interested me from the point of view of screen-plate colour photography, as it seems obvious that by using alternate layers of red, purple and green celluloid the resulting veneer would make an excellent base or viewing screen as in the Warner-Powrie process. Presumably in sufficiently large quantity the cost would not be prohibitive.—Yours faithfully,

E. H. C. ATKINSON.

November 16, 1907.

## Answers to Correspondents.

- \*.\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \*.\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \*.\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \*.\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- H. Osguthorpe, 18, King Street, Spennymoor. Photograph of Pulpit in St. Charles R.C. Church, Tuddhoe, Spennymoor.
- F. A. E. Skeen, 41, Chatham Street, Colombo, Ceylon. Photograph, Study of a Tamil Woman.
- W. H. Cole, John Street, Porthcawl, Glamorgan. Photograph of the Rev. D. J. Tiley.
- Mrs. M. A. Harrison, Hillside House, Horse Hill, Leigh-on-Sea. Photograph of Mrs. M. A. Harrison.
- Bridgman & Robbins, 2, Marina Arcade, Bexhill-on-Sea. Photograph, Presentation of the Freedom of the Borough of Bexhill to Lord Brassey by J. M. Glover, Esq.

**JNO. N. LIGHTBOURN** (St. Thomas, D.W.I.).—Autochrome plates in English and foreign sizes are obtainable from the Lumière Company, Great Russell Street, London, W.C. The process gives transparencies on glass. We have posted you a booklet on the method of working the process.

**A. J. DIX.**—The Autotype Company.

**J. W. PULLERING.**—The fault was ours. The words "will require a longer exposure than a 2 in. sitter to lens" should be deleted.

**AUTOCHROMES.**—In the "Morning Post" I read that "M. Gravier has succeeded in cutting short the manipulations (of this plate) at Stage C, by giving it a dip in a solution of sodium bisulphite.

This results in a whitish image which darkens in daylight, an excellent colour effect resulting," etc. 1. Is the manipulation cut short before or after Stage C?—i.e., is solution used, or not? 2. Are no further manipulations necessary, such as re-developing or fixing, etc.?—E. Y. E. N.

1. The plates must be treated in the C (reversing) solution before dipping in the bisulphite. 2. Only a brief washing.

**ELECTROPHOTOGRAPHY.**—Could you inform me where I can obtain particulars of specification of method of sending photographs by wire, as noticed in "Daily Mirror," etc.?—A. L. S.

From the Patent Office, 25, Southampton Buildings, London, E.C. Professor Korn's patents are abstracted in our "Patent News" on pages 257 and 772 of the present volume.

**COCKLES.**—You should read formulæ as—

Alum, 1 oz. in 20 ozs. of water,  
Or 10 gms. in 1,000 c.c.

It is hardly likely that ordinary alum has been used. Most probably it was a strong formalin hardener, say 1 to 10, or else strong chrome alum. Basic chrome alum is a powerful hardener. To obtain it, add ammonia, drop by drop, to 10 per cent. chrome alum solution, until a permanent precipitate is just formed.

**PHOTOGRAPHS ON IVORY.**—I should be very grateful if you could tell me aught on the transferring of carbon prints on to ivory. I have looked over several articles on carbon printing, and although transferring to opal is treated no mention is made of ivory. It is such an expensive substance that I do not care to experiment, and am fearful that the hot water development might injure the ivory.—IVORY.

The prints are not developed on the ivory; as to do so would stain the latter with the bichromate in the tissue. They are developed on the flexible support, and transferred to the ivory. After the picture has been developed, alumed, and dried, it is put with the ivory, in the following solution (warm):—Nelson's No. 1 gelatine, one ounce; water, twenty ounces; chrome alum, twelve grains, in one ounce of hot water. The two are brought in contact, removed, and then squeezed together, and allowed to dry, when the flexible support is stripped off.

**BUSINESS.**—The value of a business is based upon the returns, together with the net profit they yield. They are usually averaged from the previous three years. If you refer to page 382, of the issue for May 24 last, you will find an article on "Points for Consideration in Purchasing a Photographic Business." That will enlighten you specifically on the very points you raise.

**RESIDUES.**—Having considerable quantities of large size negatives and prints to handle, I shall be glad if you will please favour me with (1) full detailed instructions for recovery of silver from hypo baths; also (2) is the method the same for hypo in which plates are fixed and for that used for fixing bromide prints (the latter bath contains metabisulphite of potassium; and (3), if the method is the same, is it advisable to mix the negative and print baths during treatment or to keep them separate?—J. W. H.

The whole of the fixing bath may be mixed together, as the same treatment will do for all. The simplest, and, on the whole, the best, method of precipitating the silver is with sulphide of potassium ("liver of sulphur"). This will throw it down as sulphide of silver. No more of the sulphide should be used than is necessary, as an excess has a tendency to re-dissolve the precipitate. The best procedure is as follows:—Make up a strong solution of the sulphide, add some to the hypo, and well stir, and let subside. Then take a little of the clear solution and add to it a few drops of the sulphide. If turbidity is produced it will show that there is still silver in solution, and more sulphide must be added. Good fresh sulphide should be used, as that which has long been kept in badly corked bottles will have become deteriorated. A good test of its quality is its odour. If it "stinks well" it will be found all right. When the sulphide of silver is collected and dried it may be sent to the refiner. The silver can also be reduced by suspending strips of zinc in the hypo, but the method just described is preferable.

**REMOVING VARNISH FROM ACCESSORIES.**—I should be grateful if you could give me formula for a good detergent solution to remove (without firing) varnish (probably copal), from studio accessories, as as to be able to renovate, revarnish, etc.—**PHOTOPHIL.**

We are inclined to doubt if any photographic accessories are varnished with copal. Probably ordinary wainscot varnish was used. A strong solution of pearlsh (carbonate of potash), applied hot, will probably remove it. After well washing fresh varnish may be applied.

**ENLARGER.**—We prefer pattern A. A 5-inch lens will answer for a quarter-plate negative.

A. Z.—"Photographische Chronik," W. Knapp, Halle a/S. There is no agent in London.

C. PRITHEEN.—There is none published, and none likely to be, owing to the large proportion of "floating" photographers.

**RISEING OR SWING FRONT.**—I shall be obliged if you will inform me under which of the two following conditions a good anastigmat lens employed to take a view above its normal view in a horizontal camera, can be worked at the larger aperture to give equal definition:—1. When raised by the ordinary rising front so that its axis remains perpendicular to the plate. 2. When raised by a curved rising front so that its axis points to the centre of the plate.—W. D. B.

Under the first condition.

H. REEVE.—The developer is supposed to be made up strictly according to the formula. We suggest your chemicals are not up to the mark in purity.

**ENQUIRER.**—Apply to the Comptroller, 25, Southampton Buildings, London, E.C. We do not act as patent agents.

**ILL-USED ASSISTANTS.**—In April last I was engaged by Mr. —, of —, as operator and retoucher. I wanted £2 a week, and he offered me 35s. for a year certain, if he found my work suited him after a month's trial. This I accepted, and have been with him since. Last week he gave me a month's notice, saying the season's business was over, and he could not afford to keep on during the winter. I reminded him that our agreement was for a year certain, and he replied that he was sorry, but he could not help it, as he did very little business in the winter, and could not possibly keep me on. He said he thought he was dealing very fairly with me by giving a month's notice, when only a week was necessary. He also said he would give me a good reference. I should like to know, if you will please tell me, if I have any remedy for this shabby treatment. I have just been told that it has been the custom of Mr. — for three or four years past to engage an operator for a year certain and then discharge him when the season is over.—**HARD DONE BY.**

If the agreement is in writing, and bears a sixpenny stamp, you can claim your salary for the full term. If it was a verbal one, which we fear it is, you can obtain no redress, unless it was made in the presence of a witness who will substantiate it. Then, in the county court, you might possibly get a judgment. We have more than once warned assistants against relying on verbal engagements for a year, or a "permanency." All such engagements, to be binding, must be in writing, and bear a sixpenny agreement stamp. We have reason to believe that our correspondent's experience is not exceptional. Such conduct on the part of employers in getting services at a cheaper rate is very discreditable.

**FIXING BATH.**—A few days ago I left a few bromide prints in the hypo fixing bath, and on examining after about one hour found that the image had almost disappeared. I have since tried different samples of hypo and paper, and find that when the bath (4oz. hypo, 20oz. water), is freshly made the reducing action takes place and becomes noticeable after about 30 minutes in the bath. After the bath has been in use prints may be left for hours without any appreciable difference. I should be obliged if you could give me any explanation of the action.—**HYPO.**

Most probably your hypo is slightly acid, and in this condition bleaches the prints. As other prints carry alkali from the developer into the bath, the effect disappears.

**LENS FOR ENLARGING.**—What is the best lens to get for daylight enlarging up to 15 x 12 from all sizes? We have been using Dallmeyer's Portrait Lens, 3 B and 1 B, old make, and find great difficulty in getting edges of enlargement sharp, even when stopped down smallest, and that make such a long exposure necessary. We want a lens about 8 in. focus, which will enlarge from quarter-plate to 15 x 12, and give perfect sharpness at edges without undue stopping down, and price must not be high, and exposure necessary short.—A. E. G.

If you are not enlarging from a negative larger than half-plate, almost any good R.R. lens working at  $f/8$  will answer well. A portrait lens is not suitable for the purpose, since in many cases it is not intended to cover to the corners of the plate. Better still is an anastigmat working at  $f/5$  or  $f/6$ , any of which, as you can see from the Almanac, are listed at very moderate prices.

**CINEMATOGRAPE QUERIES.**—I have recently purchased a cinematograph, and should be glad of information on the following points concerning its use. 1. Using a lens of 4 in. equiv. focus, at what distance from the screen will it be necessary to have lantern to obtain an 8 ft. picture (length)? 2. Having this distance given, what size picture would a lens of 10 in. equiv. focus give from a standard size slide ( $3\frac{1}{4} \times 3\frac{1}{4}$ )? 3. In the event of a film breaking during exhibition, what is the method of effecting a quick repair? 4. Please recommend me to firms hiring out films. 5. Is it advisable to insure films whilst in my hands? 6. (a) What is the gauge of enclosed piece of film? (b) What are the standard gauges? 7. Would an acetylene jet with two burners be satisfactory as a luminant (Tyler's "Dreadnought," No. 1)? 8. Is it compulsory to have a fireproof screen around apparatus when showing in public?—LIVING PICTURES.

1. About 64 ft. 2. About 17 ft. square. 3. Make broken ends overlap and fix them within ordinary pin. Afterwards they can be cemented together. 4. Butcher and Sons, and many other firms do this. 5. Yes, if you want to be on safe side. 6. (a) Standard Edison gauge; (b) This is practically the only gauge used. 7. No use at all for distance given above. Would only serve for a very small disc quite close to lantern. 8. Yes, in any place under the L.C.C., and also in many places under other councils.

**RESTORING PRINT.**—Can you give me instructions as to how accompanying print can be restored somewhat? Can it be bleached and then developed? It is valued, and I must not risk its destruction. I have a good order if I can get passably good results.—PHOTOREX.

Without knowing something of the history of the print we cannot suggest any chemical method of restoration. You do not state either age of print or kind of paper. Any chemical method would involve risk of destroying the image. Why not try to produce a negative from it by contact printing?

**NORTH.**—(1) There is really no good text-book. The best is Johnson's "Retouching of Negatives and Photographs" (Marion and Co., 2s.). (2) Certainly. Apply to Houghtons or Butcher's.

**A DOG AND CHRISTMAS PHOTOGRAPHS.**—A few days ago I went out to try and get a few orders for Christmas cards, etc., taking my chap with me. I sent him to call at a house where I had done work before. When he got to the back of the house he saw a notice board; on it was "Beware of the Dog," but seeing no dog about he went on. About half between the gate and the back door the dog rushed upon him, seizing the camera cloth, tore the camera from his hand, smashing it in many pieces. Hearing the dog bark the servants came out of the house and took the dog off. I went to the front door to show the gentleman what his dog had done, but he refused to see me, so wrote him a letter asking him if he would pay for the damage his dog had done. But he has not answered my letter. Can I get compensation if I summon him? Is it a County Court job or otherwise?—J. B.

There being a notice, "Beware of the Dog," we think your man should not have gone forward; but, as the dog is evidently vicious, the owner would be liable for damages, if you can prove that the dog has done previous damage. Your action should be in the County Court.

**H. W. POND.**—Try the "Nobra" developer of the Kodak Company.

**W. GRANT.**—It is quite correct that enclosed arc lamps give a light rich in the ultra-violet rays, and so they enable rapid exposure to be given. The special construction of the enclosed arc lamp gives this advantage—you might as reasonably ask why all motors cars don't travel at sixty miles an hour! If your lamp was fitted in your studio by a competent electrician we should imagine the wiring is correct, but if the lamp was constructed by its makers to work on a 480 volt continuous current it is hardly fair to expect it to run at its best on a 200 volt alternating even though a lot of the resistance has been taken out. Why not write the makers and see if you have it fitted up to the best advantage. If the light appears yellowish to the eye you may be able to get shorter exposures by using the orthochromatic plate of the same makers, whose plates you are now employing. They only need ordinary care in development, and the experiment is worth trying.

**CARBON PRINTING TROUBLE.**—I am very pleased to note your article on "Matt Carbon." I have practised this method (opal as temporary support) for many years, and to me the soft matt result is far superior to that given by the semi-glossy flexible support. I am sorry, however, you have not said more about the final transfer. Although I have practised carbon printing more or less since 1885, I am still occasionally troubled with those small bright specks on the finished print. (1) Are those caused by air bubbles on the tissue in the first transfer, or by the same on the soaked print (on the opal), or on the final transfer paper? Any hints in this direction will be much appreciated. (2) Also, could you say where the net or renewable form of squeegee may be had? I see it is not included in Marion's latest catalogue.—W. J. B.

(1) The bright specks may be due to minute air bubbles between the tissue and the glass. If so, they should be seen when the print is dry if it is closely examined. The trouble in your case probably arises in the final transfer. It may be avoided as follows:—Soak the print (on the opal) in cold water for a few minutes, then bring the softened transfer paper in contact with it under the water, remove, and then squeegee the two together and allow to dry. In this way air bubbles are avoided in the final transfer. (2) Thornton-Pickard Manufacturing Company, Altrincham.

**ORTHOGRAPHIC LENS.**—A friend of mine, who is not a photographer, has a lens which he has offered me for twelve shillings. It bears the name of Voigtlander. It is a curious-looking thing, and I have never seen the like before. The front lens is about two inches in diameter, and in shape is like the front lens of a portrait lens, but the back is much smaller and is composed of two glasses, not cemented together. Can you tell me what the lens is, and what purposes it is suited for?—T. B. WARREN.

The lens is what is known as the orthoscopic. It is a very good instrument of its kind, and is suited for general work where great rapidity is not required. It does not give straight marginal lines; the latter are curved the reverse way to those given with a single lens, that is, it gives pincushion distortion. This form of lens has, years ago, been superseded by the R.R., which has a larger aperture, and yields straight marginal lines.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The "British Journal Photographic Almanac" for 1908 will be obtainable throughout the United Kingdom on Monday next, December 2.

The exhibition of examples of portraiture by artificial light closes to-morrow (Saturday), November 30.

Some figures of the cost of artificial lighting are quoted from a recent lecture. (P. 907.)

An account of the personal photographic portraiture of Mr. E. O. Hoppe appears on page 900.

Some reminiscences of royal photography have been published by Mr. William Downey. (P. 902.)

A showroom for professional photographic requisites has recently been arranged. (P. 903.)

Copyright grievances, the light of the enclosed arc, and the drying of oil-prints during pigmentation figure in our correspondence columns. (P. 914.)

Mr. Pirie Macdonald has recently recommended his method of recovering the metal from platinum print developer and acid baths. (P. 899.)

Self-developing plates, tripod attachments, and focal-plane shutters are among the patents of the week. (P. 909.)

The first portion of the recent Traill-Taylor memorial lecture by Mr. S. D. Chalmers appears on page 903. Mr. Chalmers took as his subject the higher aberrations of photographic lenses. Some explanatory comments on the lecture appear on page 898.

A formula for a non-abrasion developer for gaslight paper has been recommended by an American worker. (P. 905.)

M. Guéhard has suggested the application of reversal by slight exposure to daylight to the Autochrome plate. (P. 898.)

Prince Albert of Belgium has consented to become President d'honneur of the Photographic Convention at the Brussels meeting next year. (P. 897.)

## EX CATHEDRA.

### Photo-Telegraphy.

The possibilities of photo-telegraphy are very great, and in a few years we shall probably see it in use for purposes that, at the present time, we cannot even guess at. It is cheering to see a new invention greeted with enthusiasm, for, as a rule, the pessimist is much in evidence at the birth of a new idea; but still we fear that the following paragraph from "Electricity and Electrical Engineering" is, if anything, somewhat too optimistic:—"The application of 'Photo-telegraphy' for illustrations in the Press is only one of the many instances in which it may be used. It may come in handy for the purposes of Scotland Yard, and, as Professor Korn indicated, it may lead to a new craze, i.e., that of collecting photo-telegraphic cards, as, for instance, it may be used for sending the picture of a new baby from one parent to the other in the case of one or the other parent being abroad at the time of the event taking place, which would be very interesting to the mother, if she happens to be the parent who is abroad."

\* \* \*

### News for Dry-plate Factories.

A most amusing product of the sensation-mongering of the yellow journalism has reached us in the shape of a paragraph from what appears from its typography to be an American journal. An "authority," who is described as a "psychologist of the University of Chicago," is quoted as asserting the objection of men, as well as animals, to red, in proof whereof the gifted writer and "authority" gives a description of a dry-plate factory which represents these establishments something more horrid than an Inferno. Dry-plate workers, we read, "have noticed ('noticed' is good) the rows and fights and brawls that distinguished their red-light rooms." Only in those rooms, where there was a "diabolical ruby glare" (= safe light) would be heard "oaths, groans, howls of rage, the sound of crashing blows, of falling bodies." Elsewhere all would be quietude and order, but in the red-light rooms, "pandemonium." We have often been informed that the dry-plate business was no slight trial of the temper, but we have never heard that the irritation arising from it affected others than the emulsion maker and his responsible assistants. The Dantesque description we have quoted can surely have been inspired only by some brief ejaculation of a plate-maker on hearing, say, that the weir of the coating machine had failed. There is only one thing to be done to a weir in these circumstances.

\* \* \*

### Next Year's Convention at Brussels.

Every good omen appears to attend the prospects of the 1908 meeting of the Photographic Convention at Brussels. We learn that His Royal Highness Prince Albert of Belgium (the Heir Apparent) has accepted the "Presidency d'honneur" of the Convention, and that His Royal

Highness, with the Burgomaster of Brussels, the Burgomaster of Antwerp, the Burgomaster of Ghent, the President of the "Cercle Artistique," and the Secretary General, will head the list of the local committee of organisation in Brussels. The elegant suite of rooms of the "Cercle Artistique" has (by the courtesy of the committee) been secured for the meetings and trade exhibition.

**Death of Sir Henry Colville.** In the sudden death of General Colville last Sunday evening the photographic world has lost one of its most ardent amateur workers. Sir Henry Colville was not given to talking of his own achievements, but during his long and distinguished career as a soldier he has constantly found in photography a relaxation sufficiently serious for one of his energetic habits. Moreover, in conjunction with Lady Colville, he has designed cameras suitable for military purposes. At the time of his death the drawings for an instrument of almost waistcoat pocket dimensions were in the hands of a photographic friend of his, Mr. R. C. Murray, who had undertaken to advise Sir Henry Colville as to its manufacture. In the deceased General the country has lost a dashing soldier and fascinating writer, but the news of his death will have been a severe shock to those who knew him as a generous and lovable man and firm friend.

**Reversal of Autochromes.** In a note presented to the "Académie des Sciences" of Paris, on November 11, M. Adrien Guébard draws attention to his studies on the inversion of the photographic image, and suggests that the principles might be applied in the Autochrome procedure. It is known that prolonged development of under-exposure yields a positive image, as does also continuation of development after a slight exposure to daylight. M. Guébard suggests that by the application of the principle of reversal the chemical method used in the Lumière procedure might be avoided, and at the same time with the production of increased contrast and reduction of the time of exposure.

#### A New Element—Lutetium.

The value of spectrographic analysis has received further support by M. G. Urbain's discovery of lutetium. M. Urbain, who is chargé de cours and lecturer on analytical chemistry at the Sorbonne, Paris, has been working on the chemistry of the rare earths for some fourteen years. The economic and scientific importance of these has steadily increased since Auer v. Welsbach's important discovery. M. Urbain, however, has by appeal to spectrography disposed of three "elements" in this group, and, in compensation, has succeeded in splitting one of them, ytterbium, into two others. He described his results at the Société Chimique de France on November 8. In conjunction with M. Griner, he has found by chemical and spectrographic analysis that the "so-called" "bauxium," obtained from bauxite by Bayer, is a mixture of vanadium and tungsten. Continuing his spectrographic researches on the cathodic phosphorescence of the rare earths, he finds that sulphate of gadolinum, containing terbium, gives the phosphorescent bands, attributed by Sir W. Crookes partly to the "meta" elements gadolinum  $\beta$  and gadolinum  $\delta$ , and partly to new elements, ionium and incognitum. As the bands in question are obtainable by simply varying the proportions of gadolinum and terbium, the existence of other elements is not a necessary postulate. Another long series of fractionations and measurements has shown that ytterbium, discovered by Marignac, with an approximate atomic weight 173, is composed of two elements, one of atomic weight approximating 168, the other having an atomic weight greater than 174. M. Urbain has named the one neo-ytterbium and the other

lutetium, after "La Ville lumière"; both show characteristic but complex band and line spectra. In his spectrographic work he uses a quartz spectrograph, with prism and lenses of quartz, working to wave-length 200 mm., the iron arc being photographed as a standard of comparison.

#### THE ABERRATIONS OF LENSES.

THE Traill-Taylor lecture by Mr. S. D. Chalmers, the first part of which we reprint this week, is a very important one to the optical student, as it deals with matters that are quite outside the scope of the ordinary text-book. It pays special regard to what are styled aberrations of the higher orders, which, in certain circumstances, have most important effects on the behaviour of photographic lenses. The text-books, however, generally confine themselves to aberrations of the first order, and by ignoring the others lead students to think that the correction of the first order aberrations is all that is necessary to produce a perfect lens.

The meaning of the terms first order and higher orders is perhaps quite incomprehensible to many readers, hence an attempt at explanation may be useful. The aberrations of the first order are the five commonly described under the names of spherical aberration, coma, astigmatism, curvature, and distortion. We dealt briefly with these in our leader of March 22 last, in which we touched on the von Seidel conditions of correction, including the much-discussed Petzval condition. Up to a certain point a great deal is known about these aberrations. Thus, for example, spherical aberration is known to increase in proportion to the cube of the aperture, so long as the aperture does not exceed a certain size, and while this rate of increase is maintained the defect may be described as spherical aberration of the first order. With bigger apertures, however, the ratio is incorrect. It is too small. Hence, if we allow only for the correction of aberration of the first order, a residue of uncorrected aberration will remain, which may be truly described as due to aberration of a higher order. Then, again, as Mr. Chalmers points out, if we attempt to compensate the spherical aberration of a positive lens by combining it with a second one possessing negative aberration, the two will not exactly balance one another at all apertures, hence a residue of higher order aberration will be left. Taking a particular case, if the aberration is, balanced at a small aperture a residue will be found at larger apertures that will increase as the fifth power of the aperture, this more rapid rate of increase justifying the use of the term higher-order.

It is manifest that a residual aberration such as this, though very small in amount at a moderate aperture, will, owing to its rapid increase, become very important at big apertures; therefore, a compromise has to be effected if a big aperture is necessary.

The general principle adopted for the correction of the higher order aberrations is that of compensation. A little first order aberration is left or introduced to correct that of higher order, which practically means that the theoretical conditions for the correction of aberrations of the first order are not always fulfilled perfectly. This explains why it is sometimes advantageous to apply the Petzval condition more or less exactly, and sometimes better to depart from it. The production of a perfect photographic objective is a matter of compromise and approximation throughout. The large apertures and the wide angles of view employed introduce difficulties that do not exist with other instruments such as telescopes, and these difficulties are mainly due to the higher order aberrations, the effects of which do not admit of rigid calculation owing to the extreme complexity of the mathematical work involved.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1908.

Edited by GEORGE E. BROWN, F.I.C.

On Monday next, December 2, THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1908 will be obtainable from the counter of every photographic dealer and chemist, and from those of a good many booksellers throughout the United Kingdom. This forty-seventh annual issue of the ALMANAC is noteworthy for one or two reasons. First, the publishers have succeeded in reducing the ungainly bulk of the monster. Secondly, they have been prevailed upon by the editor to place all three indexes together at the end of the book. Thirdly, they offer a contents of more than usual interest, to which every justice has been done in the way of printing, paper, and arrangement for rapid consultation. Both the text and advertisement sections prove the claim of the publishers that the ALMANAC is the reference book of photographers to be no empty boast, but a fact accomplished by an autumn's incessant care of details, correspondence, and attention to the multifarious responsibilities involved in the production of 25,000 copies of a book of 1,382 pages. But not to dwell on these

herculean labours, some few features of the new ALMANAC may be mentioned:—

The new screen-plate processes of colour photography. By the Editor.

Epitome of Progress.—A systematic compendium of the hints, methods, and formulæ of the year.

New tables of weights and measures, chemicals, exposure, plate-speeds, etc., and new optical rules and formulæ.

Formulæ for the photographic processes, revised throughout, and with much additional information.

An abstract of the instructions of the leading plate and paper makers.

Reviews (illustrated) of recent novelties in apparatus.

The whole of the new features are more quickly at the disposal of the reader of the ALMANAC in consequence of the two innovations already mentioned, viz.:—

- (1). The reduced size of the "Almanac."
- (2). The collection of all indexes at the end of the book.

## FINAL NOTICE.

Our publishers desire us to say that almost the whole of the edition of the ALMANAC is booked for delivery December 2. Any further orders and any re-orders should be in their hands immediately in order to be assured of execution.

## PLATINUM RESIDUES.

[Pirie MacDonald, who is nothing if not practical, under the attractive title "Seven Per Cent. Discount on consummation is not one of negotiation, though the alert of a highly-developed business sense, but is based on the acid baths.—Eds. "B.J."]

You know, of course, that the whites of the print have as much platinum in them as the blacks, while the print is in the printing frame, and that in order to prevent the whites becoming black, we dissolve out the platinum, and that the first acid water does most of the work.

## The Money in Platinum Paper.

Then it follows, that if your prints are composed of one-half whites and one-half blacks, that the acid is dissolving out one-half of the platinum that was originally put on the paper and if you are making many white grounds, that it is dissolving out more than one-half, sometimes more than three-quarters, of the original platinum, and when you print with white margin, or vignettes, more yet, and most photographers throw that acid wash down the sink—and platinum worth five hundred and twelve dollars a pound!

When I started this article I knew that a big proportion of the readers would say, "stuff," "nonsense," "another waste-saving scheme, that will turn out as all others have—a lot of trouble, and no result; Theory!" But I made a test of exact quantities awhile ago, and found that from 100 rolls we got \$72 in cash for the precipitate at a cost of \$2.25.

On a basis of \$10 a roll—true, some papers cost less, but it's not far out as a basis—at \$10 a roll, we have a saving of within fraction of 7 per cent., and money talks.

How quickly we would turn our good ear to a salesman who would offer us our platinum paper at a discount of 7 per cent. or 6 per cent., or even 5 per cent., off any price we were buying at—so don't quibble with my \$10 a roll basis.

contributes to the "Photographer" a characteristic screed "Platinum Paper." His method of attaining this desired "photographer of men" may pride himself on the possession of a commonplace process of recovering the wasted platinum from

## The Method of Extraction.

The real way to do it is to take a twenty-gallon stone jar—not a dinky little five-gallon butter crock, or a keg that may spring a leak, and get mussy—but a new twenty-gallon jar—pour into it the first acid wash both from sepia and black, and if you have any developer to throw away, pour it in too.

Then cut two sticks and make a cross of them—large enough so that they will bridge the top of the jar, and won't fall in. and suspend from the cross by a stout string some strips of zinc (sheet zinc at a hardware store costs 30 cents per pound, but you can buy scrap zinc from photo-engravers, the odds and ends cut from their plates, at 5 cents per pound). Let the zinc hang down to within, say, three inches from the bottom of the jar, but don't let it touch the sludge, for it will become coated and inactive.

When the solution has stood twelve hours it will settle and should become colourless, but if it remains to any degree yellow, it still has platinum in suspension, and you must add, say, one-half ounce of muriatic acid. Scrape the zinc free from any coating it may have accumulated, and examine the solution again after another twelve hours. This, however, will rarely be necessary.

When the liquid has become colourless, dip out most of it, and let it go down the sink, being careful not to disturb the whitish-gray sludge that has been thrown down on the bottom of the jar, and when you have used 100 rolls, take out the mud, drain it on a cloth, which you have tacked on a stretcher, letting the drip go back into the jar, and when dry it is ready for the refiner—and if you are more careful than we were you will get a better discount from your paper bill than we did, and if you do, please let me know at once, for I need the money.

PIRIE MACDONALD.

## A MODERN NOTE IN PORTRAIT PHOTOGRAPHY.

[In giving an account of the entrance of one of the younger pictorial workers into professional portraiture, we could wish to reproduce some examples of Mr. Hoppe's work, an aspiration which the exigencies of speedy production compel us to check. Several typical portraits by Mr. Hoppe appeared in our contemporary "The Photographic Monthly" for October last in illustration of an appreciation by Mr. Snowden Ward. Possessors of the current "Photograms of the Year" may turn also to the example of Mr. Hoppe's work on page 132.—Eds. "B.J."]

THE recent revival of the "one-man" professional photography had its first beginnings in the United States. When the phrase "one-man portrait photography" first reached this country, some three or four years ago, and when the circumstances which it

Falk, Hollinger, Macdonald, or Strauss, do not follow their profession on the narrow line of personal attention to every operation, though their photographs show individuality. In Great Britain it cannot be said that the above type of "one-man

A CORNER OF MR. E. O. HOPPE'S STUDIO, KENSINGTON.

represented were understood, there was the feeling that the term was a catch-phrase, and the mode of appeal to the public only one prepared for the special purpose of offering the same thing as something different. In other words, the one-man photographer—the photographer who does everything from first to last with his own hands—entered the modern field quite convinced that the idea was a good thing, and that there was money in it. In proof whereof he offered to teach the little ins and outs of the business to anybody for a consideration. What is the exact number of this class of person in America at the present time we cannot say, but we believe his species is limited. The individualist leaders of portrait photography in the States, such as

photography exists at all. Examples we have of "one-man" professional portraitists, but the process of their creation and the works by which we know them are as different as possible from those associated with the same phrase across the Atlantic.

Moreover, it is the fact that the men in this country who have taken up portrait photography with the conviction that the portrait must be all their work from first to last have not done so in order to galvanize an existing portrait business, but have taken up portrait photography, or had it thrust upon them because it was more congenial to them than other occupation which, it may be easily assumed, were more profitable. The explanation of their existence, it would seem, is, first, the growing

public which can appreciate the difference between a photograph which has tonal qualities and composition and one which is innocent of these attributes of the artist-craftsman, and, secondly, the sincerity of purpose on the part of the "one-man" photographer. He aims at work of an order which he hopes may not be denied the title of "art": he aims at making a portrait which is something of a character-sketch of his sitter: he aims at photographs which have beauty of tone and line. It so happens that a public (size not stated) is ready to pay for these qualities, and hence studios such as that at 10, Margravine Gardens, South Kensington, inhabited by Mr. E. O. Hoppe, whose work is worthy of serious notice as an "example illustrating" of the new movement afoot in professional photography.

Photograph by]

MR. E. O. HOPPE.

[S. Elwin Neame.

Everything which has just been claimed on behalf of the "one-man" photographer can certainly be set down to the credit of Mr. Hoppe. Trained in the art schools of Munich, he was forced for a time to enter commercial life. He is almost ashamed to say that his serious study of portrait photography goes back but three years. But in that time he has worked and studied incessantly—with what result his portraits at photographic exhibitions have shown. In taking up photographic portraiture as a profession he is fortunate in adding to his technical skill a lively imagination and great earnestness of purpose. These, perhaps, would avail him nothing did not his bent lead him to prefer a likeness to an impression. The unrecognisable "study" of a sitter evidently has no charm for him, as we saw at once on looking through a portfolio of prints of both sitters and models. In the latter no less than the former there was scarcely an instance in which the photograph could not have been called a satisfactory portrait.

A dull November mist lay over the plains of South Kensington on the morning when we made our pilgrimage. At No. 10, Margravine Gardens only a small brass plate, "E. O. Hoppe, Studio," gave a sign of the occasion of our errand. Mr. Hoppe's studio, formerly that of Alfred Garrett, R.A., has nothing about it save a camera in one corner to suggest photography. Cheerful comfort, the fireside where one is a welcome guest, most aptly describes one's first impression of it. Then one looks around and notices that it is furnished with all regard to harmony between floor- and wall-coverings, the few tables and chests, and the pictures on the walls. Among the latter are a fair number of portraits by Mr. Hoppe. From these one sees that Mr. Hoppe is no faker or trickster in portraiture. He has no prevailing recipe for every occasion. He takes a dark background or a white one, and you may see one or the other used for a man's portrait or a woman's. If he has a *penchant*, it is towards setting a light object against a light ground, or a dark against a dark, and indulging in subtleties of tone-contrasts. And then he will burst away with some big effect, got by a bold contrast. The hands are a great feature in Mr. Hoppe's portraiture; they occur in the majority of his

"Accessories" (real) of the modern portrait photographer. A photograph in Mr. E. O. Hoppe's Studio.

work, and are evidently one of the means of characterisation which he employs. Of retouching Mr. Hoppe makes as little use as possible, and in the case of men's portraits, it may be said, none at all. Most of his negatives are taken with a slight diffusion of focus, but Mr. Hoppe grants himself very little latitude in this direction, and holds it as a rule that diffusion should not be pushed to an extent which destroys texture and structure. Nothing very novel or revolutionary in these methods; nothing which has not been talked about over and over again: Mr. Hoppe makes no pretence to have discovered new principles to be using unique apparatus, or to have devised new processes. Indeed, to claim anything for himself beyond an absorbing interest in his work is the last thing one would expect of this most modest recruit to the ranks of professional photographers. We wish Mr. Hoppe and all like him who are wedding their ideas of art to their practice of portraiture the best of luck. Such enterprise is in the nature of an experiment, and courageous are they who make it. Nevertheless, it should encourage Mr. Hoppe that the number of people who desire portraits such as he can give them is daily growing. Meanwhile all those who interest themselves in the progress of photography as a medium of portraiture will not lose sight of Mr. Hoppe and his work. It will be a surprise if he disappoints the achievement of the past three years: his influence is bound to be felt in portrait photography.

## FORTY YEARS A ROYAL PHOTOGRAPHER.

[The recent remarkable photographs of Royalties taken at Windsor during the visit of the German Emperor and Empress by Messrs. W. and D. Downey, have led to Mr. William Downey, the head of the firm and the doyen of Court photographers, to communicate some of his experiences to the press. The following article appears under his signature in the "Daily Dispatch."]

"You'll get on in life," said John Bright to me many years ago in South Shields, my birthplace, and the town in which I first started business, but little did I think then I should ever come to London to be photographer to the Court for over forty years, or that I should ever have the honour of photographing so unique a gathering of Royal personages as I did on Sunday last.

Never in all my life have I had the opportunity of taking such a remarkable group. The pictures were taken in the Red Drawing Room at Windsor Castle after luncheon. We were not allowed to make any preparations until half-past one, and

undue fuss. This was what the late Queen liked best, and His Majesty the King takes after her in that respect. When he honours me with a sitting he tells me at once how many minutes he has to spare, and, although the time is generally very brief, the sitting is always got over successfully. Although His Majesty has a very keen dislike of unauthorised snap-shots, he is a very patient sitter when facing the camera.

The late Queen Victoria so much liked one photograph of herself which I had taken that she had it reproduced three time in twenty-five years—that is to say, she assumed exactly the same pose as she had taken in the original photograph.

I took one of the first flashlight photographs ever taken in this country, in the days when such inventions were only just thought about. It was on the occasion of an operatic performance at Windsor Castle, and the Royal Family showed great interest in the experiment.

### The Picture Postcard.

I was also the first to take a series of cinematograph pictures of the late Queen whilst her Majesty was walking in the grounds of Balmoral, and we had a machine made and showed the pictures at Windsor Castle on a subsequent occasion; and we also took the first photograph of a Royal wedding in a church. It was on the occasion of the wedding of the King and Queen of Norway.

On one occasion I took a very fine photograph of the late Queen, with the late Empress Augusta of Germany, but for some reason or other, I do not know what, we had not permission to publish it. In consequence I was obliged to decline an order for a million cabinet copies.

Photographs do not sell so well as that nowadays—at least, not in that form. To-day the sale is enormous, but very quick, and a particular "boom" is all over in a very few days. The illustrated papers clamour eagerly for any new photographs of Royalty, and we sell hundreds of thousands of copies as picture postcards.

Whilst on the subject of picture postcards, I may note, although it has nothing to do with Royalty, but just as an instance of the craze, that we sold two and a half million postcard pictures of a well-known beauty in eighteen months.

### The Queen's Domestic Tastes.

British Royalties are very domesticated, and seem to like domestic photographs best of all. Queen Alexandra, whose photographs are the most popular of any Royal person, is nearly always taken with her grandchildren or her pet dogs, and the Prince and Princess of Wales have also a fondness for similar groups.

My most popular Royal portrait is a group of the late Queen and her family, entitled "Four Generations," but another very popular picture was that taken very many years ago of the present Queen with the baby Princess Royal on her back. A great many people refused to believe that it was a genuine portrait. "You have got somebody to pose for it," they declared. It took a tremendous hold on the public, and over 300,000 genuine photographs of it were sold.

### Albums of Royal Photographs.

Many years afterwards I had the honour of taking a similar photograph of the Princess Royal with her baby on her back

Photograph by]

MR. WILLIAM DOWNEY.

[W. & D. Downey.

we had then to put up the electric light plant, fix the cable, and make all our arrangements before the Royal visitors had finished their meal. Then we took the photographs, five or six exposures in all. It was at our suggestion that the unique group of eight Kings and Queens was taken, and after that we had to do the best we could with a general group.

The first Royal photograph I ever took was one of the present Queen, more than forty years ago, at the York Agricultural Show. This was followed by the then Prince of Wales's command to go to Abergeldie, and the photographs taken there were so successful that the late Queen sent for me to go to Balmoral, and gave me her first sitting. Since then I have been taking Royal photographs nearly all the time.

### The King before the Camera.

I think I can attribute a great deal of my success with Royalty to my being perfectly natural, and by avoiding all

a unique record, I should think, in the way of photography. I have many photographs of the other celebrities taken at regular intervals from the age of short frocks up to middle age.

One of my most cherished possessions is an autograph album, in which many Royal personages, and nearly every celebrity

of note during the last forty years, have inscribed their names, in many cases adding some pretty little compliment to myself.

I have besides a unique collection of miniatures of all the Royal personages of Europe, and I have the Victorian and Coronation medals, presented to me by his Majesty the King.

WILLIAM DOWNEY.

## THE ABERRATIONS OF PHOTOGRAPHIC LENSES.

The Tenth Traill-Taylor Memorial Lecture.

It is a great privilege to share in the efforts of this society to commemorate the name of J. Traill-Taylor, and to share in its endeavour to further the progress in those departments with which his name is associated.

The subject to which I will invite your attention to-night is one that particularly appealed to him, and his great gifts of clear and concise exposition would have eminently qualified him for the work of expressing in systematic form the results of recent work on this subject. But, alas! this is impossible, and it has fallen to my lot to attempt such an exposition.

have a diameter (in inches) of not less than  $1/25000$  the F. number of the lens. In photographic lenses no attempt is made to reach the standard of definition, and we may regard a diameter of  $1/1000$  inch† as giving sufficiently sharp definition in the centre of the plate; under these conditions we could magnify the image from four to six times without appreciable falling off of definition, since the eye cannot appreciate the difference between a spot  $4/1000$  in. and one smaller in diameter unless they be magnified.

As regards general definition over the plate we may consider a standard of  $4/1000$  inch or  $1/10$ th mm. as giving excellent definition,

Fig. 1.

Fig. 2.

Fig. 3.

Although the results which refer to aberrations of higher order have been obtained independently, some of the results had already been obtained by other writers, particularly by Dennis Taylor, Von Rohr, and Schwarzschild.\* The theory of aberrations which I propose to describe differs only in detail from that of Schwarzschild.

I have always endeavoured to regard the subject of aberrations from the point of view of the user or designer of photographic lenses, and to me a defect of a lens is important in so far as it produces or tends to produce bad definition or distorted images on the ground glass or photographic plate. From this point of view the definition is determined by the size and shape of the "spot" or "patch" of light which is received on the photographic plate, from each point of the object. The distribution of light within this "patch" will also be of importance, as it will affect the appearance on the plate under different conditions of exposure; with under-exposure the fainter parts will not affect the plate. We should also know the effects on the definition of small changes in the position of either the object or the plate.

In some optical systems a limit is set to the size of the "patch" of light, depending on the nature of light. The patch of light must

and except where photographs are to be magnified for measurement purposes, there is very little to be gained by improving the definition beyond this limit. In fact, since the same type of system, increased aperture or field can only be obtained at the expense of the definition it is frequently desirable to set a rather lower standard for the sake of increasing the aperture or the size of the plate covered.

Whichever of these standards be chosen it is impossible to reproduce on the same plate the objects in different planes with the same degree of sharpness, and probably the photographer would not be pleased if his lens did this. But all objects in one flat plane can be produced with reasonable definition, provided the aperture and plate be not too large, as compared with the focal length.

Again, it is necessary that the image should be similar to the original object. Thus the patch of light from a point on the object must come to a certain point on the plate, depending on the position of the object and the focal length of the lens. We call this point the ideal image of the object, and the whole of the light from the object point should pass through this point.

The distance between this point and the actual point at which any ray strikes the plane of the plate is called the "error" of the ray. This error may be obtained by calculation when the constants of the system are known, or it may be obtained by direct measurement. But though we could obtain information about any chosen ray in this way, we cannot deduce the error of any other ray. Fortunately, it

\* Dennis Taylor, "A System of Applied Optics"; Schwarzschild, "Untersuchungen über geometrischen Optik"; Von Rohr, "Die Bild-Erzeugung in Optischen Instrumenten."

† This is an approximate only, as the outer edge of this disc would be very faint.

is possible to obtain the error by adding together the effects of a number of aberrations. These aberrations may be considered as producing a certain displacement of every ray, and their effects in any given system will depend on the position of the image, the point on the aperture of the stop through which the light passes, and a constant depending on the construction of the system. The effects of each of these aberrations can be found for any ray as soon as the effects of each of the aberrations separately can be found for a standard ray.

In the case of a single lens the errors can be expressed as the sum

Scale 1 m/m.  
Fig. 4.

of the effects of the five aberrations with which we are all familiar, but when in photographic lenses we have almost balanced out the aberrations for one lens by almost equal but opposite aberrations in another lens, there still remain errors, which can be expressed as the sum of nine aberrations, depending in a different way on the aperture ratio and angular field.

By aperture ratio I mean the fraction which has a numerator 1, and the F number of the stop for denominator; by angular field, the

Fig. 5.

distance of the image from the centre of the plane divided by the focal length, or rather the angle of which this is the tangent.

If we divide the aperture into a number of very narrow circular zones, the stop will be set at a definite F number when each one of these zones is just exposed. We will call the corresponding aperture ratio, the aperture ratio of this zone.

The five aberrations which occur in the ordinary way for a single lens of reasonable aperture and field will be referred to as the aberrations of the First Order, since for these fields and apertures they are by far the most important.

The other aberrations, which are said to be of the Second Order, become of importance only when the aperture or field is excessive or when, as in ordinary photographic lenses, the aberrations of the first order are wholly or nearly corrected. The effect of the aberrations on a given ray will depend on the aperture ratio of the zone through which it passes and the angular field, but it will also depend on the actual position of the point on which the ray strikes the aperture. For this reason it is desirable to determine the figure which is traced out on the focal plane by the light from a small circular zone on the stop.

In Fig. 1a the outer circle represents a zone of 30 mm. diameter on a lens of 330 mm. focal length; the inner circle represents a zone of one-half the diameter. The effect of the ordinary spherical aberration calculated from the ordinary formulæ is shown in Fig. 1b, while 1c shows the circles formed on the focal plane by the light from two zones. It will be noticed that the smaller circle is only one-eighth of the diameter of the larger, and this arises from the fact that the spherical aberration increases as the cube of the aperture ratio. But if we examine this lens we find that the central definition is not properly represented by the Fig. 1c, even though monochromatic light be used.

We suppose that there must be some other aberration effect, and if we evaluate the spherical aberration of a single lens, for example,

Fig. 6.

one of 100 mm. focal length and 45 mm. aperture, we note that the spherical aberration disc is not strictly proportional to the cube of the aperture when the aperture becomes large. In Fig. 2 a curve has been drawn showing the diameter of the circular zone of light corresponding to each point of the aperture for one special lens of 100 mm. focal length. The curve which would represent this aberration if it were strictly proportional to the cube of the aperture is also drawn.

For apertures of radius 10 mm. there is no appreciable difference; even at a radius of 15 mm. the difference is negligible, and even at 22.5—i.e., 45 mm. diameter or F 2.2—the difference is only about 1-10 of the actual aberration. But when such a lens is used in conjunction with a negative lens to produce an achromatic combination, the total focal length might be as great as 300 mm.; thus giving for the aperture ratio 1-6.6. At the same time an attempt will be made to compensate as much spherical aberration as possible by the other lens, but it will not generally happen that the differences which occur when the aperture is increased will be of the same amount so as to balance in the two lenses. The result will be that, as the aperture increases, a small residual amount of spherical aberration will be found. This aberration would, if the spherical aberration were

balanced at a low aperture, increase as the fifth power of the aperture; that is, there is an aberration of higher order, and this limits the possible increase of the aperture.

In Fig. 3 curves are drawn representing the diameters of the circles on the focal plane corresponding to the various zones on the stop. It will be noticed that in one curve the abscissa increases as the cube of the aperture, and in the other curve as the fifth power of the aperture; the . . . . curve represents the difference or resultant effect.

Instead of choosing the curves so that the spherical aberration is corrected for small apertures—i.e., before the differences of Fig. 2 begin to be important—the curves have been chosen so that the light through the outside zone comes to a point—i.e., the larger circles of Figs. 1c and 1d are equal but oppositely placed.

In this way the diameter of the patch of light has been reduced to about one-fifth of the value we would have obtained by correcting the spherical aberration for a small aperture.

This principle of leaving a certain amount of a defect for an intermediate value of aperture or field in order to compensate a defect, which increases more rapidly with the aperture or field, is of very great importance in designing photographic lenses. In fact, we leave small amounts of the first order aberrations for the sake of compensating some of the effects of higher order. It is the aberration of higher order that really limits the aperture for which we can correct, as any attempt to increase the aperture, say from F 5 to F 4, means an increase in the residual aberration in the ratio of ( $\frac{4}{5}$ )<sup>3</sup>, i.e., 3:1.

Thus we see that there are two defects of the nature of spherical aberration, one depending on the third power of the aperture ratio, the other on the fifth power; and, in the particular lens system I am using as an illustration, these defects have been arranged so that they compensate as nearly as possible. When we examine the effect of these two aberrations towards the edge of the field we find that they depend on the actual value of the aperture ratio at these places;

and as the actual aperture of the beam is diminished, owing to the oblique incidence the figures are no longer circular, but elliptical.\*

*Coma.*—When we examine the image formed by a single lens, we frequently notice a one-sided blurring out of the image, either toward the axis or away from it; this effect is due to the presence of the aberration of coma; and, in fact, any one-sided flare may be attributed to this defect, though in many cases it is the result of an error in centring rather than an aberration.

In the case of a single lens the coma effects will vary as the square of the aperture and the first power of the angular field, and even in complicated systems there will be an aberration of this type; though some of the defects will probably be due to aberrations which vary as the angular field and the fourth power of the aperture or the square of the aperture and the cube of the angular field. The effect of ordinary coma is very curious; a half zone on the objective will produce a complete circle on the plate, and the centre of this circle will be at a distance equal to its own diameter, from the spot produced by the centre of the aperture, as in Fig. 4. The final figure produced by all the zones is also shown in Fig. 4.

The coma of higher order which depends on the fourth power of the aperture is similar, except that the point corresponding to 0 is at a distance from the centre equal to  $\frac{2}{3}$  radius (Fig. 5). In combination with ordinary coma the whole effect is no longer so regular; and the larger circles are smaller or larger than they would be in coma of the ordinary type. The coma which arises from an extension of the angular field depends on two constants, and so may have various forms, but it is best considered after we have dealt with the aberrations of astigmatism and curvature of field, and oblique spherical aberration.

S. D. CHALMERS.

(To be continued.)

\* The circles are diminished in the ratio of  $\cos^2 \theta : 1$  in one direction and  $\cos^2 \theta : 1$  in the other for the first order aberration, and  $\cos^4 \theta : 1$  in one and  $\cos^4 \theta : 1$  in the other for the second order aberration.

## NON-ABRASION DEVELOPER FOR GASLIGHT PAPERS.

[The following article, in the "Photographic Times," deals with a formula for a developer of gaslight papers which shall avoid the occurrence of so-called "abrasion" markings. The writer points out that it supplies also a easy check on the misuse of the fixing-bath.—Eds. "B.J."] ]

RECENTLY, in one of the photographic magazines, there appeared a formula, which was given as the regular Velox formula for making glossy gaslight prints without abrasion marks. It recommended the addition of ten grains of potassium iodide to every fluid ounce of developer. Upon trial, the formula was found to differ widely, in the results obtained, from the regular Velox N.A. developer. Paper printed the usual length of time, with the same light, negative, and under exactly the same conditions that were used with the Velox N.A. developer, was found to develop very slowly and with a sickly yellow tinge. The final result, after fixing, showed an apparently much undertimed print with a rather rusty tone. Thereupon, a series of experiments was begun, with the object of finding a developer which gave the same results chemically and pictorially as the ready-mixed developers that cost 50 cents per 4oz. bottle.

### A Colour Test for Exhausted Fixer.

The desired end was soon reached, and the formula that is given in this article will be found to possess all the good qualities claimed for any developer now on the market. It entirely prevents abrasion marks, improves the tone of the finished print; but what is perhaps best of all, it furnishes the printer with unmistakable evidence of the complete fixation of the print. When the print comes up in the developer it assumes a canary-yellow colour, which in no way affects the density of the print. The print is developed to exactly the same apparent density as is done when ordinary developer is used. The yellow colour, not having any appreciable effect on the print's density, cannot confuse the operator, and becomes of great importance when the print is placed in the fixing-bath, as it completely disappears when the print is thoroughly fixed, and not before, leaving it a beautiful blue-black, the tone so much desired by all gaslight printers and so hard to get by amateurs. This colour, then, removes all the elements of uncertainty from the operation of fixing, and also gives warning when bath becomes exhausted,

as in that case it will not disappear until the prints have been placed in a fresh solution.

It is often necessary, in commercial work, to get gaslight prints out in the shortest possible time consistent with proper fixing and washing. By using this developer, the print may be taken out of the hypo as soon as the fixing is completed, thus saving many valuable minutes and making it certain that any deterioration of the print later will not be due to insufficient fixing, but to the washing. Even here the element of chance has been removed, as the Velox people publish a formula for testing prints to find when they are thoroughly washed. The formula is:—

Water (distilled) .....	8 ounces.
Potassium permanganate .....	8 grains.
Caustic soda .....	7 grains.

Drain the prints into a graduate and pour a few drops of the above solution in it. If the colour of the solution remains pink the prints are done, but if the water turns green they are not ready to come out of the water.

### Preparing Non-abrasion Developer.

Now to return to our developer. It has been found that it is good for glossy and matt surface papers alike. In fact, after using this developer once, one is not at all inclined to return to the plain developer as the non-abrasion has undeniable advantages over any developer that does not make it possible for the worker to accurately decide when the print is thoroughly fixed.

However much the results differ from the ordinary Velox developer, the composition differs but very slightly. The formula is:—

Water .....	10 ounces.
Metal .....	7 grains.
Hydroquinone .....	30 grains.
Sodium sulphate (dry) .....	110 grains.
Sodium carbonate (dry) .....	200 grains.
Potassium iodide .....	10 grains.
Potassium bromide (10 per cent. solution) ..	18 drops.

The chemicals should be dissolved in the order named. The developer should be used full strength. No additional bromide is necessary, as the solution contains all that is required for a properly timed print. If the tones are not all that they should be, the fault is due to either under or over exposure. It is important that the developer and the fixing-bath should both be kept as cold as possible during the summer months. The temperature of these solutions has a direct effect on the colour of the prints. Warm developer gives brownish-blacks, while cold developer gives blue-blacks.

HARRY S. HOOD.

#### PROFESSIONAL PHOTOGRAPHY AT MESSRS. HOUGHTONS LIMITED.

MANY who know the High Holborn establishment of Messrs. Houghtons Limited may not be aware that a department has recently been set aside in that building for the purpose of coming directly into touch with professional photographers, and of receiving their personal instructions and commissions. Messrs. Houghtons have placed this department on an upper floor, and made it inaccessible to the unauthorised customer, so that the professional may discuss his wants and such minor matters as discounts without the chance of his conversation being overheard by, say, one of his own customers—not such an improbable event in the more public retail shop of Messrs. Houghtons. A brief tour of inspection which we recently paid to this new sub-section of the Houghton business proved to us it was not simply a “move” on the part of the firm to heighten the effect of their claims to be professionals’ providers, but was in fact a step which needed to be taken to permit of adequate opportunity of inspecting the many articles of their own manufacture produced for the professional, and largely for him alone. Though the department is not many weeks old, it already contains an installation of enclosed arc lamps which a photographer can arrange to use with a view to testing the suitability of the lamps for his own studio or for the printing of his negatives. Of backgrounds and general studio accessories we saw a great variety, and were particularly pleased to find Messrs. Houghtons giving a prominent position to oak-panelling as a background for the portrait studio. Such a substitute for the painted ground allows the photographer to give a warm and home-like appearance to the studio in contradistinction to the chill with which the painted ground invariably strikes a sitter. The panelling

supplies quite enough gradations of light and shade to make it adaptable to the requirements of the portraitist, and £5 or £6 will purchase an area of it sufficient for the customary use of the studio.

In the way of apparatus, Messrs. Houghtons may justly claim to be peculiarly well able to supply the professional at first hand from their own factories, and an enumeration of their many specialities

A Corner of the Professional Showroom at Messrs. Houghtons Ltd.

would occupy a whole issue of this journal. Reference may be made, however, to a new model of studio camera of the firm's manufacture which can be seen in the professional department. Its solid construction, range of movements, and handsome appearance may be commended to the notice of the business photographer. In the matter too of other modern necessities for the professional, such as rapid

A View of Messrs. Houghtons Ltd.'s Recently Arranged Professional Department.

bromide printers, dry-mounting machines, and portfolio stands for the reception room, the purchaser will be able to see and select at his leisure.

One new and important line of goods is specially noteworthy on account of its economy of time and labour—we refer to the various forms of card index and vertical-file cabinets. These modern tools of the business house are peculiarly applicable to the business of the photographer, since they permit of a precise estimate of the orders in hand being made in a few moments, and the state of any given piece of work being ascertained at a glance. Those who recollect a recent article by Mr. Pirie Macdonald in our pages will be interested in hearing of the adaptation to British studios by Messrs. Houghtons of the system commended by him. A card is then allotted to each sitter on which is first entered the name and address, and the date for the sitting in the case of an appointment. The negatives taken all receive the same "sitting" number, but are further distinguished by *a, b, c, d*, etc., according to the position. The card then passes into the section for "proofs in hand," thence to "proofs out," and is then transferred to a section or special holder for "orders in hand," being finally filed with a complete record of the transaction. This is what the successful Mr. Macdonald calls "keeping tabs on your business," and the means provided for it by Messrs. Houghtons allow of it being employed in an amplified or restricted form, according to the needs of a business.

But it is in the choice of mounts more than any other requisite for his business that the professional will appreciate the opportunity of examining what is available, since even the best kind of illustration is as ineffective as verbal description in giving a useful idea of a mount. And Messrs. Houghtons can show an enormous variety, the majority of which, it may surprise some to hear, are of their own manufacture. We have spent the best part of a morning in turning over a collection of specimens and have nothing but commendation for the great variety of styles and the convenient way in which a specimen of each mount is mounted in conjunction with particulars of the prices and the colours, and other sizes and styles of lettering in which it can be obtained. The facility of choosing suitable mounts is certainly one strong inducement to pay Messrs. Houghtons a visit.

### AN EXPEDITION INTO EGYPT.

ARRANGEMENTS are being made in Berlin for a scientific expedition to Assouan, to start in January next, under the direction of Dr. Adolf Miethe and Dr. Kurlbaum. The party is going prepared to make a number of meteorological observations in the clear atmosphere of Upper Egypt, and photography, also colour photography, will figure largely in its programme.

Dr. Kurlbaum intends to make a number of photoheliometric observations with an apparatus of his own construction, and to undertake new measurements of solar constants.

Dr. Miethe and an assistant have drawn up a lengthy syllabus of work for themselves. They propose to study, by means of colour photography, the sunset phenomena, which in those latitudes are particularly regular and beautiful. For this purpose they will take two three-colour cameras, with lenses of different focal lengths, in order to register in colours the changes in the phenomena at frequent short intervals. It is hoped that in this way the typical course of the sunset will be registered more accurately than has hitherto been the case. Observations are also to be made on the ultra-violet of the solar spectrum at different positions of the sun. Previous work which has been done in this subject has been with apparatus in which the shortest wave-lengths (the absorption of which by the atmosphere was to have been measured) could not be defined with the necessary sharpness, owing to stray light in the spectrograph obliterating the finest detail on long exposure. The spectrograph to be used by Dr. Miethe is fitted with lenses of quartz and a prism of calc-spar, in order to obtain greater dispersion in the ultra-violet than with the customary quartz prism. In order to cut out stray light on long exposure, a second prism, identical with the first, but with its base crossed, is placed behind the first quartz prism, so that the resulting spectrum is formed by both prisms and the stray light completely removed.

Observations are also to be made on the lines of the zodiacal light,

for which a camera, mounted on clockwork mechanism, is to be used for keeping the instrument in parallelism during photographic exposures on the spectrum. By this means, in conjunction with a telescopic finder, it will be possible to make exposures of one hour in length. It is hoped that by the use of ultra-sensitive plates, the precise limits of the zodiac light and its alterations in size and shape will be fixed.

Still another apparatus is to be used for the study of the apparent flattening of the sun at the horizon, this latter, a description of telephoto lens, giving a very sharp image of the sun of one inch diameter. The apparatus is provided with fine adjustments for the simultaneous registration of the sun's altitude, and the photograph will thus allow of the measurement, from the horizontal and vertical diameters, of the horizontal refraction, the exact estimation of which would appear to be easy by this method.

The expedition will remain in Assouan for six weeks, and will be lodged in one of the disused forts.

### ARTIFICIAL LIGHTING.

(Abstract of a paper read before the Royal Cornwall Polytechnic Society, Falmouth.)

AFTER an historical survey, the author said his object was to show the provision science and commerce have made for those villages and country houses where coal gas and the electric light are not available. Proceeding he said, as early as 1872 carbide of calcium, from which acetylene gas is generated, was manufactured commercially by fusion of lime and carbon in the electric furnace. It was not, however, until the last few years that the apparatus for producing the gas was sufficiently perfect for general use. It has, however, now been very largely adopted for country house lighting, and indeed, although to a less extent, for village lighting. The apparatus is comparatively low in first cost. It consists of a generator wherein the gas is evolved, and a small gasometer which receives it, the action of which regulates the quantity of gas generated in proportion to the number of lights actually in use. There is in addition to this, generally, a purifier containing materials, the object of which is to separate the sulphur from the gas and so prevent smell. It is entirely automatic in its action. In use acetylene gas has all the advantages and disadvantages of ordinary coal gas, while in addition it has a very characteristic smell, and is more highly explosive. The apparatus is very simple, and anyone can with ordinary care manage it. The process of removing the used carbide is a very dirty one, and very nasty smelling. Still, in the evolution of gas-making plants, it has served a very useful purpose, and has been highly valued by many who have, and are still using it.

The most recent advance in gas-making plants which has been made is known as the Litz gas lighting apparatus. Its object is to produce gas for heating and lighting purposes, from petrol or other suitable spirit. It is a marked advance. The producing plant consists of a motor blower which drives a current of air to the carburettor containing the spirit, which has to be evaporated. From this carburettor the gas passes into a small gas-holder, the real object of which is to maintain a steady supply of gas to the burners. The amount of gas stored in the smallest possible quantity, the whole apparatus being entirely automatic, and produces the exact amount of gas required by the number of lights in use. The motor is of the hot-air type, the heat being obtained from the gas that is generated. It is one which will run for a week without lubricating or attention, the work it does being automatically regulated by the lights in use. The whole apparatus occupies only a few square feet of floor space, and may be placed in an outbuilding. The gas is the product of oil vapour and air in so dilute a carburetted mixture, that it can only be used with a patent burner in conjunction with a cotton or platinum mantle.

Owing to the quantity of air that is mixed with the oil vapour, there being 1.52 per cent. hydrocarbons, 98.48 per cent. air, the whole of this air necessary for consumption being actually carried in the gas-pipes, the result is that no air is taken from the room to support combustion. Further, the mixture of gas and the air is so complete, and the form of burner such that combustion is practically perfect. There is no trace in the after-products of the deadly carbon monoxide, and the percentage of carbon dioxide, for the reasons

above stated, is so small that it is declared to have no deleterious effect on the health—a claim which no coal gas or acetylene lighting system has ever before been able to successfully substantiate. The perfect combustion produced by the form of burner is such that there are no particles of carbon escaping into the air, which with the action of carbon dioxide has such serious effects on pictures, books, decorations, etc. This gas is found in practice not to produce blackening. Another distinct feature is that owing to the weakness of the gas, it cannot be lighted at a leakage, neither can it be exploded in the event of an escape into the room, as with the coal gas. Further, it has no unpleasant smell. It also has a high efficiency for heating purposes. Its last claim is that it is enormously cheaper than any form of gas lighting for equal illumination. The manufacturers claim that with spirit at 1s. per gallon, 1,000 candle power hours of light are produced for 1½d., whereas with the best form of incandescent gas lighting it costs 3d. The writer from a considerable practical experience does not hesitate to confirm these claims. A plant is on view in the exhibition, and its properties can be clearly demonstrated.

The efforts of inventors have not been lacking in their desire to make electricity suitable for the use of isolated residences or mansions. The latest improvement in this direction has been that gas is generated on the spot, and used in the gas-engine, the most popular form being that known as suction gas. The advantage of this has been, while somewhat increasing the first cost, to enormously reduce the lighting cost, as will be seen from the table given below, and the fact that makers claim to produce a horse power of energy for one-tenth of a penny per hour, which is roughly equal to ten 16 c.p. lights, or put in another form, one hundred 16 c.p. lights for one hour for one penny. The generating apparatus is very simple; indeed, it is the simplest part of the whole plant. The plant, however, which can be seen in the hall is entirely outside the means of a very large number of people. Within the last two or three years the petrol motor, of a somewhat similar form to that used in motor cars, has been applied to the production of electric light, by being used in combination with a dynamo. Apart from its distinctive feature of high speed, which reduces the size and weight of the plant, as well as reducing the cost of the dynamo, the running of the engine is so simple that it is not found objectionable to use the engine for running the lights direct, a small battery only being provided to supply the lights necessary when the household have retired to bed. These engines run at considerably higher speed than the ordinary gas-engine, so that the dynamo can be coupled direct to it without the use of a belt, and without very considerably increasing the size of the dynamo. The effect of these characteristics has been to reduce the weight of the plant as compared with a similar gas-engine installation to probably one-sixth, and the floor space to an equal extent.

Then again, this engine is so easily started and stopped, requiring so little attention, and making comparatively little noise, that we can dispense with the large storage battery, as the engine may be allowed to run till the users retire to bed, the battery then supplying the night lights. Perfect steadiness can be obtained when running direct in this way by a proper arrangement of the battery, so that it will, while being charged at times when only a small number of lights are being used, have the effect of taking up the extra volts of the dynamo, or actually supplying the lights should the dynamo actually drop down or a greater demand be made than it can easily supply. This plant properly fitted and complete is found to answer all requirements where a reduced outlay is desirable, and its effect has been to reduce the first cost to anything from one-fourth to one-sixth, as compared with the gas or oil engine plant before described.

I shall hardly obtain my object without giving figures which will enable one to compare the costs of lighting by any or all of the apparatus to which I have referred. The true value of such figures is, however, largely affected by the distinctive characteristics of the lights to which they refer, such as attendance necessary to produce the light, the first cost, the deteriorating effect on the object in proximity to it, as well as on decoration, thus adding to the real or actual cost; at the same time not forgetting the possible incidental increase of cost due to the more or less danger from fire and explosion of the system, more or less hygienic perfection. Most of the figures here given are results of experiments of leading scientists, or from the tests made by independent professional engineers at the instigation of the manufacturers. I have given these figures in the form of the

price per candle power one-thousandth of a penny, as being the most convenient form:—

Giving cost per candle power per hour in thousandths of a penny.

	Thousandths of a 1d. per candle power
1. Paraffin at 8d. per gallon, common lamp.....	55
2. Paraffin at 8d. per gallon, modern lamps .....	9
3. Candles, composite, at 8d. per lb. ....	160
4. Gas, Bray's burners, gas at 3s. per 1,000.....	11.25
5. Gas—75 p.c., Welsbach, averaging 48 c.p.....	3.125
6. Electricity, at 4d. per unit, 16 c.p. lamp .....	14.28
7. Electricity, arc lamp, 500 watts, 875 c.p .....	2.37
8. Acetylene gas, ½ cubic feet burner of 24 c.p., 1,000 feet, costing 40s.....	10.0
9. Litz spirit gas, spirit 6d. per gallon .....	1.0
10. Litz spirit gas, spirit 1s. per gallon .....	1.5
11. Electric incandescent tantalum lamps .....	8.6
12. Electric mercury vapour lamp .....	2.04
13. Electric flame arc lamp .....	0.92
14. Petrol dynamo, incandescent lamps .....	6.05
15. Suction gas engine dynamo .....	0.58

E. E. ALGER.

## Exhibitions.

### SOUTHAMPTON CAMERA CLUB.

OWING to the darkness which enveloped the neighbourhood of London in Wednesday in last week, the following concluding part of the report of the Southampton Exhibition was delayed in transmission:—

As usual, the "open" competitive classes have been well supported by the exhibiting public, and in one or two instances the newer school of exhibitors have forced recognition from the judge by superlatively beautiful work, although for the most part the old-time winners have well sustained their reputations.

The Misses Aitchison have each two exhibits of excellent quality, especially noticeable being "The Ghetto—Prague," and "Houses of Parliament." Mr. Herbert Bairstow shows four good prints exquisitely mounted, and Mr. F. W. Beker's two pictures are fine pictorial renderings of topographical subjects—a naval review and a schooner-rigged yacht. Mrs. Barton's "Little Paul" takes a well-deserved award, but her two other prints are of almost equal merit, and Mr. W. H. Bullock has a splendid mist effect in "Hazy Morning on the Medina." Mr. Graystone Bird's slides are up to that worker's high standard, and the same may be said of the slides by Messrs. Thomas Carlyle and W. A. Clark. W. Coats, jun., sends a picture of the great liner "Mauretania" leaving the Tyne, Mr. R. L. Cocks shows a fine woodland picture, entitled "In the Pinewoods," and Mr. and Miss Crouch are also represented by good work. Mr. Henry J. Comley is rightly regarded as one of the world's leaders in "colour" work, and "Strawberries," which takes an award in the pictorial class, is perhaps the best "three-colour" picture that has yet been produced. The Rev. T. A. Cooper wins, in the "Hampshire" class with "Pictures," a well thought-out genre study, and A. K. Dannatt makes a decided hit with "The Early Boat," though "The Close of Day" runs it very close for popularity. Mr. Dan Dunlop exhibits a magnificent head study, "The Old Professor," and Mrs. R. Dunlop, H. M. Haines, C. J. Hankinson, and the Rev. R. E. V. Hanson are responsible for several fine prints. Mr. C. H. Hewitt has received an hon. mention for "Flecked with Sunlight," which, with "Water Meadows," another picture by the same artist, is quite one of the gems of the "show." Mr. E. T. Holding's best picture is unquestionably "Mother's Veil," one of his inimitable child studies; and Miss Brenda Johnson exhibits a most attractive, albeit remarkably weird, figure study which rightly bears the title "Fantasie." Mr. J. B. Johnston, Colonel Johnstone, and Messrs. G. A. Jones and Fred Judge must be highly commended for some excellent work, and two sets of beautiful slides have been sent in by Mr. Ellis Kelsey. Mr. H. Mortimer Lamb, a Canadian worker, shows three fine portrait studies, and the remarkable professional work of Herr R. Dührkoop

has proved to be as popular with the judge as with the general public, for the portrait of "Lady A. v. F." has been granted one of the principal awards. Mr. Arthur Marshall's "Pastoral" is another picture that has gained for the artist one of the coveted rose-bowls, and though it has not obtained the same hall-mark of excellence, "Nocturne" is equally popular with visitors to the exhibition. Messrs. S. E. Max Mills, Robert Marshall, and E. W. Pannell are all strongly represented; Mrs. E. Peake shows a fine technical rendering of "Clematis"; and Mrs. Ambrose Ralli sends six frames of great interest, the best being, perhaps, "Cologne." Mr. V. E. Morris, with an award, and Dr. G. H. Rodman, with an honourable mention, have both received distinction for their splendid lantern slides, whilst other awards and "mentions" in the lantern slide class go to Messrs. G. J. T. Walford, Alfred Taylor, and A. G. Thistleton. Miss Hilda Stevenson also takes an award for "The Last Chapter," an exquisite picture in the new oil process, although little, if any, better than the "Study in Oil," Miss Stevenson's other exhibit.

Mr. L. J. Steele takes an award in the Hampshire class with his "Garden of Allah," which is only too well known. It is a great pity that the undoubted merit of this picture prevented the judge from passing it over, for this is the third occasion upon which a print from the same original negative has been exhibited in competition at Southampton. Exhibition committees should frame a rule to preclude such work from competition.

Honourable mentions in the "open" class go to H. Y. Summons and Miss Agnes B. Warburg, who maintain a high class of work; Mr. Alfred Taylor receives an award for his splendid natural history work in "The Life Story of a Kingfisher"; and good landscape, genre, and still-life work is exhibited by Mr. F. A. Tinker, especially noteworthy being "Whitby," "Binding the Wheel," and "Honesty."

Some interesting Indian pictures are contributed by the Tuberaj of Tippetah; and other exhibitors we may note in passing (for space will not permit of a detailed account) are Miss Bolton, Norman L. Craig, Geo. Easonsmith, and Dr. Grindrod; G. H. Capper, F. C. Hayes, Dr. A. T. Lakin, J. Maddison, C. W. Pearson, W. J. Penrose, Mrs. E. Perry, Walter Selfe, Miss Kate Smith, Mrs. Sutherland, A. J. Taylor, P. G. Terras, A. W. Ward, and Harrop P. Wight.

The loan collection comprises examples of the pictorial work of J. H. Anderson, J. Craig Annan, Harold Baker, Mrs. G. A. Barton, Walter Benington, A. H. Blake, W. R. Bland, David Blount, Archibald Cochrane, Reginald Craigie, W. Crooke, Miss Constance H. Ellis, F. H. Evans, A. Horsley Hinton, Fredk. Hollyer, Chas. Job, Alex. Keighley, Arthur Marshall, F. J. Mortimer, Cavendish Morton, J. C. S. Mummary, the late H. P. Robinson, F. M. Sutcliffe, W. Thomas, J. B. B. Wellington, and J. M. Whitehead. Some of the seventy-nine pictures are old favourites, others, again, are this year's work, but one and all are masterpieces of the different schools of photographic art, and the names of the artists are alone sufficient to show that Southampton has, in this loan section, perhaps the finest collection of British work that has ever been gathered together. The "colour" section fully shows what strides have been made in this branch of photography, and a fine lot of work has been contributed by Miss Acland, E. T. Butler, Henry J. Comley, George E. Brown, A. W. Everest, and A. G. Rider; and also by the Autotype Company and the Rotary Company in their respective processes.

It is exceedingly gratifying to Mr. Kimber and the local committee to know that Mr. Horsley Hinton, who judged the exhibition, thought most highly of the way the pictures were arranged and hung; and it is a happy augury for the general success of the show to hear nothing but praise for the very thorough and careful judging, which has given complete satisfaction on every hand.

**THE PHOTO-SECESSION.**—An exhibition of photographs by the members of the Photo-SeceSSION is being held at the Little Galleries of the Photo-SeceSSION, 291, Fifth Avenue (between Thirtieth and Thirty-first Streets), New York, closing December 30. The Galleries are open from 10 a.m. till 6 p.m. daily, Sundays excepted. Between 10 a.m. and 12 a.m., and 2 p.m. and 3.30 p.m., Autochrome colour photographs by members of the Photo-SeceSSION are being shown.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been made between November 11 and 16:—

**CINEMATOGRAPHS.**—No. 25,074. Improvements in and relating to cinematographs. Robert Thorne Haines, Chancery Lane Station Chambers, London.

**PROJECTION BANDS.**—No. 25,165. Metallised photographic bands for projection by reflection. Edouard Dupuis, 52, Chancery Lane, London.

**COLOUR SCREENS AND PLATES.**—No. 25,396. Improvements in the manufacture of screens and colour-sensitive plates, films, or the like, for photographic "process" printing, and like purposes. John Fuller Spong, 18, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SELF-DEVELOPING PLATES.**—No. 24,667, 1907. The invention relates to the application of developer to the back of a plate or other sensitive surface. Among the claims are:—

1. Separation of the acid and alkaline parts of the developer by a neutral or acid, paint-like substance.

3. The spreading of the developer on a separate sheet.

4. Distributing the acid substance of the developer at the edges of the plate, with or without tinting or colouring.

6. The use of hydroxylamine and an ammonium salt in self-developing plates.

7. The use, with the acid constituents of the developer, of acid, sulphites, or acid and sugar-like bodies, either separately or together.

8. The use of a bicarbonate as the alkaline ingredient of the developer.

As an example of the mixtures employed the following may be given:—

The acid constituent A may contain the reducing agent:

Metol ..... 1 grain.

Hydroquinone ..... 2 grains.

Milk sugar, mannite, and other sugar like preservative ..... 1½ "

Bisulphate of soda or a bisulphite ..... 1½ "

Starch partly boiled and partly in grains 6 "

Water in sufficient quantity to give a paint-like consistency on a thorough incorporation or grinding of the ingredients.

Instead of metol and hydroquinone, other reducing agents may be employed.

The alkaline accelerator B may contain the following ingredients:—

Carbonate of soda or bicarbonate of soda 10 grains.

Gum arabic ..... 2 "

Water in sufficient quantity to give a paint-like consistency to the mixture upon grinding.

The inert or slightly acid separating material C may contain the following ingredients:—

Sulphate of lime or sulphate of baryta ... 2 grains.

Gum arabic ..... ½ grain.

Water in sufficient quantity to form a paint-like mixture on grinding.

The above-mentioned quantities of A, B, and C respectively are such as are suited for coating a quarter-plate surface, or a surface measuring about 3in. by 4in.

When the separating layer, C, is to act not merely as an inert buffer between the compositions A and B, but also as a definite chemical barrier to intercept the passage of any alkali from the coating B to the coating A, the addition of a small amount of an acid to the composition, C, is desirable—for example, from about one-tenth to one-fifth of a grain of such an acid as tartaric, citric,

or the like, but if desired one-fourth of the sulphate of lime or baryta may be replaced by bisulphate of lime, making the composition sulphate or lime or baryta  $1\frac{1}{2}$  grains, bisulphite of lime  $\frac{1}{2}$  grain, gum arabic  $\frac{1}{2}$  grain, water in sufficient quantity.

According to the modifications shown in Figs. 2 and 3, the distribution of the coatings is such that the reducing or acid constituent, A, is brought near the margin, and the alkaline constituent, B, occupies the main area of the plate, but A and B are separated by an intercepting material, C, as before. One of these marginal arrangements is often desirable in the case of films or paper. When, however, the marginal material consisting of the acid constituent is brought to the face of the sensitive material, as explained above, the support and sensitive film then act as a means of separating the two constituents of the developer.

In making the improved separate sheet bearing the developing materials it may frequently be desirable, instead of painting or spreading the materials in sections, areas, strips, or margins on the same side of a sheet of paper or cloth, to employ an impervious film or sheet as a separating medium and spread the acid constituents of the dry developing preparation on one side and the alkaline constituents on the other side. If thin paper be employed it may be soaked in a gelatinous solution, the gelatine being then made insoluble by a chromium salt or formaline and varnished with celluloid varnish on the side adjacent to the acid composition. Coating separate sheets and cutting out the requisite portions and attaching them together is a convenient alternative to sheets covered by separate areas. The back of the sensitive surface, plate, film, or sheet may be coated uniformly or all over with one of the two elements or constituents of the dry developer—namely, the acid constituent or the alkaline constituent—the other constituent being on a separate sheet of the kind already mentioned.

In all cases the alkaline constituent must be in such abundance as to thoroughly neutralise or more than neutralise the acid constituent, and any acid in the intermediate composition.

In practice ordinary bicarbonate of soda or a mixture of bicarbonate of soda with bicarbonate of potash or with bicarbonate of lithia and made or mixed up to a convenient consistency with sugar, gum, or the like serves admirably. Thomas Bolas, 60, Grove Park Terrace, Chiswick, London, W.

**TRIPOD ATTACHMENTS.**—No. 695, 1907. This invention relates to means for fastening two articles together of the type wherein a bolt carried by one article is adapted to enter a recess provided in the other, such bolt being split and adapted to be expanded within the recess so that a head provided on the end of the bolt will engage with a shoulder formed in the recess and thus hold the two articles together.

The object is to provide an improved form of connecting device whereby a camera can be quickly and effectively secured to the tripod, and be as readily detachable therefrom. Under normal

conditions or when the structure is not in use, the shank 28 is turned so as to permit the spring plate 26 to act upon the bolt sections and hold them in closed condition. The head is then small enough to pass into the lower end of the collar 35 in the bed 34 of the instrument. Consequently, to secure such instrument to the tripod, it is only necessary to place it upon the tripod head, allowing the head of the bolt to pass into the collar by forcing the closure 45a inwardly against the action of the spring 47a.

When so positioned, a quarter turn of the knob 31 rotates the cam 29, and separates the head sections 23 against the action of the spring. When so separated, said head sections 23 are engaged over the retaining shoulder 38a. It will be evident that this is a quick action device, and that it constitutes an effective connection between the two parts. Moreover, the bolt sections are not only separated, but are held in the separated relation, obviating any danger of the connected parts becoming uncoupled. Furthermore the instrument can be rotated on the tripod or placed thereupon without regard to its direction, and without in any manner affecting the security of the connecting means. Nathaniel Bennett Stone, Outlook, County of Yakima, Washington, U.S.A.

**PRINTING FRAMES FOR FLEXIBLE NEGATIVES, ETC.**—No. 1,359, 1907.

The device consists of a front sheet of celluloid and a flexible opaque backing sheet, each sheet having end transverse pieces of wood, the sides of which are plane and without tongue or groove. The end pieces of the backing board are adapted to fit within the space formed by the end pieces of the front sheet, and to lie parallel and in close juxtaposition the one with the other. Means are provided for bending both sheets. Charles Jennings Hillman, No. 6, Dyers' Buildings, Holborn, London.

**COLOURING CINEMATOGRAPH FILMS.**—No. 9,306, 1907. The invention

relates to a machine which consists of three special arrangements, the concordant movements of which effect the mechanical colouring of the films by means of perforated or cut-out bands of which the number corresponds successively to those of the colours which are to appear on the film.

The first arrangement consists in making the bands to move directly above and in contact with the film to be coloured. These two elements, the film and the cut-out band being displaced together by reason of their common lateral or other perforations. The second arrangement is a number of colour-feeding devices, by which feeding is produced in an intermittent manner so as to colour successively a certain number of images before the colour is exhausted.

The third arrangement is represented by a combination of an upper mechanically moved brush with a lower fixed brush which have for their purpose the taking of the colour by the one above and the discharging from itself of any possible surplus on the one below, as well as equalising the colour taken at the same time then afterwards following a continuous or alternate movement of rotation, distributing the colour used on the projection film through the cut-out parts of the perforated band. R. W. James for the Compagnie Générale de Phonographes, Cinématographes et Appareils de Précision, 5, Rue Richempanse, Paris.

**FOCAL-PLANE SHUTTERS.**—No. 2,485, 1907. The invention relates to focal-plane shutters of the type in which both the blinds pass during either exposure or re-setting from a closed position at one fixed point to a closed position at another fixed point independent of the size of the aperture between their contiguous edges.

In shutters of this type one of the blinds (the "upper") is wound on to a roller located above the lens aperture, and this blind has tapes attached to the two sides of its lower edge, the other ends of which are attached to a spring roller below the lens aperture; the other blind (the "lower") is attached to a spring roller below the lens aperture and has tapes attached to the two sides of its upper edge which tapes are wound on to a roller above the lens aperture. The two rollers above the lens aperture are geared each to one of two gear wheels concentrically mounted on the same shaft on the side of the shutter case, so that according as the gear wheels are positioned with relation to each other at any given time, so are the blinds positioned with relation to each other and the space or opening (if any) between them is determined, thus regulating the exposure.

Hitherto in apparatus of this kind there have been several drawbacks, one of the most important of which is that the position of the two blinds in relation to each other is liable to alter during the process of exposure; this being caused, for example, by the lower blind travelling faster than the upper one, in which case the space between the blinds will be increased. It has hitherto been found impracticable to remedy this defect by supplying the lower rollers (i.e., the rollers below the lens aperture) with springs of different strengths, and making the stronger spring act as the operative one in effecting the exposure, as this is unreliable in

working; but according to the invention the two blinds are so connected together otherwise and more securely than by friction during the exposure that it is impossible for the space between them to vary in any way; whilst the said connection is released at the end of the exposure to allow the edges of the blinds again to come together (i.e., the lower edge of the upper blind to overlap the upper edge of the lower blind) so that on re-setting the shutter the blinds will be drawn across the lens aperture in such closed position. Arthur Lewis Adams, 26, Charing Cross Road, London.

### New Trade Dames.

**PROEX**.—No. 296,760. Photographic cameras and apparatus included in Class 8. John J. Griffin and Sons, Ltd., Kemble Street, Kingsway, London, W.C., photographic apparatus and paper manufacturers. October 3, 1907.

**BRANORA**.—No. 297,566. Cinematographic apparatus. Charles Urban, 48, Rupert Street, London, manufacturer. October 30, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Development of Autochromes with Three Solutions.

I have been experimenting for some time (writes Mr. A. J. Woolley in "Photography") with a view to reducing the number of solutions used in development of autochromes, and have succeeded in bringing so to a very close degree. Probably a few more experiments will perfect the process.

The developer used is rodinal. Pyro-alcohol ammonia is very wholesome on account of its rapidly oxidising properties, and also on account of the great tendency to air-bells.

Briefly then, I exposed two plates for the same time, developed as usual. Then I took two drams of rodinal in twenty-four ounces of water—1 in 12—and developed for six minutes at a temperature of 60 degrees. I then poured the developer back in the saucer, reversed the image as usual, turned up the light and poured the original rodinal developer. This I let work for six minutes, fixed the plate, and fixed as usual. When dry I compared the two plates. Result good. The rodinal-developed plate was not quite so brilliant as the other, but in all other respects quite as good, and it did not seem to require intensification. The slight loss of brilliancy is due to faulty exposure. The light fell slightly while exposing the second plate, so I think if a little more exposure had been given and the developer had been allowed seven minutes instead of six the two plates would have been equal. At any rate, if the original-developed plate had been developed by itself, and I had not another plate for comparison, I should have been quite satisfied with it, the rendering of colour being excellent.

### Mounting with a Ruling Pen.

A ruling-pen is required (writes Mr. A. E. Tendell in "The Photographic Monthly") and a tube of secotine. Both may be purchased for a shilling. A short flat rule and a basin of water and sponge are also required.

Squeeze a little of the secotine into an egg-cup and thin with a little water until of the consistency of cream. Charge the ruling pen with some of this mixture by means of a fine camel-hair brush. Dip a bit of stick sharpened to a fine point. The prints being already trimmed and lying in a pile face down, take the top one and along the whole length of the four back edges rule a fairly thick line under one-eighth of an inch thick, using the rule as a guide. The line of adhesive is to extend to the extreme edge of the print, and must not be kept even a little way in. If the adhesive does not flow it is too thick and must be thinned; but beware of making it too thin, or the prints will not stick. When all are ruled in this manner let them dry before proceeding. When dry, lay the print before the mounting is done in this way. With the sponge and water damp the face of the mount, and while still wet lay the print (face up, of course) quickly in position; a piece of

clean blotting paper is then placed over it, and the whole placed under light pressure.

Do the other prints in the same manner, placing one on the other as they are completed and maintaining an even pressure as the pile grows. In half an hour or even less they will be dry.

## New Books.

"The A.B.C. Account Book for Retail Businesses." Published by J. McQueen and Co., Moat Road, Leicester.

The thousands of professional photographers whose knowledge of bookkeeping is limited, or who have not the time to devote to the elaborate method of double entry, should welcome Mr. J. McQueen's system, which one might almost term a short-cut to bookkeeping, whilst at the same time giving reliable results. The system adopted appears to be the acme of simplicity and conciseness. The account book, which is now enlarged and in its fifth edition, is divided into sections ruled and arranged to extend over a period of twelve months. It can be commenced at any time during the year, and enables a person to tell at once exactly how his business stands. The price of the book, strongly bound in half leather, and containing copious explanatory notes, is 7s. 6d. post paid. A set of examples, exhibiting in detail one year's working of the system, is included free of charge with first orders, whilst a prospectus explanatory of the system is obtainable free.

"Toning Bromides." By C. Winthorpe Somerville. (Second Edition.) London: Dawbarn and Ward, Ltd. 1s. net.

The revised edition of this useful little book contains a multiplicity of toning formulæ which are sorted out into three sections—verified formulæ, selected formulæ, and miscellaneous formulæ. This is a useful mode of classification, as it enables us at once to distinguish the formulæ that the author specially favours and has personally tested from the rest.

In some passages we think the author is somewhat astray, as, for example, when he asserts that with platinotype you can get a doubtful apology for a sepia, but only with a tremendous amount of uncertainty. Then again, in speaking of washing the prints, he suggests that if washing in running water is inconvenient, frequent changes, extending over about double the time, should be given. We would rather say that washing in frequent changes is far more rapid than washing in running water. Another slip is the statement that citric acid must not be kept in too concentrated a solution, otherwise a fungous growth occurs. As a matter of fact, such a growth appears rapidly in a weak solution, such as 10 per cent., while a strong 50 per cent. solution may be free from it for an indefinite time.

Many of the formulæ in this book are probably unknown to a number of workers, hence it should prove interesting as well as useful to those inclined to experiment.

**HELD OVER.**—Owing to pressure on our space a number of reviews of apparatus and materials, news items, etc., have to be held over. These include a description of several new printing papers and a number of news paragraphs of special interest, and will appear in our columns next week.

**THE CHRISTMAS NUMBER** of the "Christchurch Weekly Press" is an excellent example of the continued progress which is taking place in the journalistic world of New Zealand. It is now some years since the first copy of this publication's Christmas Number reached us, and during that period we have noted, year by year, the steady improvement, both of the text and illustration portions of its pages. The illustrations of the 1907 issue, however, are of an exceedingly high standard, and the printing of both text and illustrations might put to the blush that of many similar publications issued in this country. The cover is an excellent example of colour printing, and the whole of the contents, both letterpress and illustrations, gives the English reader a good idea of New Zealand scenery, industries, and domestic life. It is accompanied by a coloured illustration of The Wharfs, Wellington, 30 inches by 15 inches in size. The price of the whole is one shilling.

## New Materials.

**"LILYWHITE" CHRISTMAS POSTCARDS.**—A series of greeting postcards suitable to the Christmas season has been sent us by the Halifax Photographic Company, Halifax. They are issued in the glossy, gas-light, and P.O.P. of the Lilywhite band, and are obtainable with a selection of four different mottoes. An illustrated circular, posted by the Halifax Company on application, shows the designs, and quotes prices for these cards.

**SCALOID AUTOCHROME CHEMICALS.**—A few weeks ago we reviewed a very compact and useful set of Autochrome chemicals, in fluid and scaloid form, sent out by Messrs. Johnson and Sons, of Cross Street, Finsbury. In the review we had to draw attention to a mistake in the instructions relating to exposure. We now understand that the instructions have been reprinted and the mistake rectified. The contents of the case have also been modified as regards the frilling preventative. Instead of the cake of paraffin, which was intended to be melted so that the edges of the plates could be dipped into it, Messrs. Johnson now enclose a tin of waxing paste. This is applied by taking up a little on a soft cloth and rubbing it well into and over the edge of the plate for a space of  $\frac{1}{4}$ -inch. It is then removed before varnishing by the simple process of wiping it off with a soft rag. This is a more simple process than the other, and though there is some doubt whether Autochromes are now liable to frill, Messrs. Johnson and Sons are to be commended for making their outfit as complete and convenient as possible.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, NOVEMBER 29.

Sutton Photographic Club. "The New Colour Photography." A. P. Hoole.  
Aberdeen Photographic Association. "Stromoll Printing." Wm. Mackay.  
Wakefield Photographic Society. "Rotary Carbograph Paper."

#### MONDAY, DECEMBER 2.

Scarborough and District Photographic Society. "Y.P.U. Portfolio of Prints."  
Bradford Photographic Society. "Rambles in Upper Wharfedale." Thomas Ryder.  
Catford and Forest Hill Photographic Society. "Pictorial Photography." Rev. F. C. Lambert, M.A.  
South London Photographic Society. Lecturette Competition.  
Harrow District Photographic and Scientific Society. "Autochrome Plates." W. G. Cullen.  
Luton Camera Club. "Rotary Carbograph Paper."  
Equitable Photographic Society (Oldham). "Photographic Chemicals."

#### TUESDAY, DECEMBER 3.

Royal Photographic Society. "The Florence Heliographic Plate" (The Warner-Powrie Process.) John H. Powrie.  
Sheffield Photographic Society. "Ozobrome." Thomas Manly. Photography Competition Prize Lantern Slides.  
Rotherham Photographic Society. "Birds in the Garden." Rev. Bernard Butler, S.J.  
Stafford Photographic Society. "Elementary Pictorial Photography." Herbert A. E. Hay.  
Kelisley and District Photographic Association. "Through the Canadian Rockies." H. Day.  
Worthing Camera Club. Carbon Demonstration by F. J. Stedman, with the Illingworth Tissue.  
Wishaw Photographic Association. "Photographic Chemicals."

#### WEDNESDAY, DECEMBER 4.

Bristol Photographic Club. "Lenses." R. W. Thomas.  
Mill Camera Club. "Lantern Slide Making by Reduction." W. Mansfield and W. Swindon.  
Fuln Photographic Society. "Exhibition of Prints and Slides."  
Borough Polytechnic Photographic Society. "The Photographic Lens." C. P. Gozard and the Tasmanian Society's Slides.  
Leeds Camera Club. "The Platinotype Process." The Platinotype Co.  
Everton Camera Club. "Among the Dutchmen with a Camera." J. T. Ferguson.  
Central Technical College Photographic Society. "Photomicrography." G. Roche Lynch.  
South Suburban Photographic Society. "Photography in Natural Colours." T. K. Grant, F.R.P.S.  
Coventry Photographic Club. Amateur Photographer (1907) Prize Slides.  
G.E.E. Mechanics' Institute Photographic Society. "Rotary Carbograph Paper."

#### THURSDAY, DECEMBER 5.

Rodley, Farsley and Calverley District Photographic Society. "Microscopic Photography." Wm. Robertshaw.  
Wimbledon and District Camera Club. "After-treatment of the Negative." E. W. Taylor.

Tunbridge Wells Amateur Photographic Association. "Scaloids." Johnson and Sons.  
Bath Photographic Society. Practical Evening.  
Stenheim Club. "Oil Processes." G. E. H. Rawlins.  
Liverpool Amateur Photographic Association. "The Theory and Practice of Time Development." W. E. Slater.

Handsworth Photographic Society. Amateur Photographer Prize Slides.  
Widlotherian Photographic Association. "Irish Life and Character." H. W. K.  
Longton and District Photographic Society. Photography Prize Slides.  
Richmond Camera Club. "Reducers." G. Ardaseer.  
North West London Photographic Society. "Rotary Carbograph Paper."  
Baltham Camera Club. "Photographic Chemicals."

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 26, the Rev. F. C. Lambert, M.A., in the chair. A lecture on the elements of photo-micrography was delivered by Mr. F. Martin-Duncan, who interestingly explained a number of points in the photographic use of the microscope, and showed a number of examples, including three autochromes, illustrating the methods recommended.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—The first general meeting of the session was held on Wednesday, November 20, when Mr. G. W. O. Howe took the chair. Mr. Illingworth, of the well-known firm of the same name, gave a demonstration entitled "The Three Z's" (Zigas, Zelvo, and Zigo), which was much appreciated by all present.

SOUTHAMPTON CAMERA CLUB.—Meeting held November 25, G. E. H. Rawlins lectured on oil printing. Mr. Rawlins first laid down the procedure of sensitising the print, which consisted of specially coated paper the gelatine coat of which was of extra thickness. This prepared paper was sold in an insensitive condition, the bichromate solution by which it was sensitised was one of five to five per cent. Sensitising was effected by a two minutes immersion of the paper, which became thoroughly sensitised without being thoroughly dry. The exposure speed when under the negative was eight times that of ordinary P.O.P., and a faint image was obtainable similar to platinum. After exposure the print was to be soaked thoroughly in water, anything up to twelve hours being permissible, the sensitiveness of the print vanishing immediately it was immersed. Mr. Rawlins proceeded to take a print out of the sensitising bath and then laid it on wet blotting-paper, it being essential that it should be kept wet while the paper was being pigmented. This pigment, which is specially prepared, was then worked into the print, the principle being that the high lights rendered insoluble by exposure rejected the oily pigment, while the shadows in the varying tones accepted it. The pigment was imposed by stiff-haired brushes by two methods, one a percussion action which Mr. Rawlins called "hopping," and which was done by a spring hand the other by dabbing, a firm stippling pressure. It was advised that the image be faintly produced by the previous method, the pigment being obtained from a palette, then the shadows made in by the heavier touch, and the varying tones of the picture produced by the hopping method, the effect of which was to take or put on the pigment according as the brush was charged or the touch light or heavy.

Mr. F. E. GERMAN has taken over the business of Mr. H. G. May, photographic studios, 11, Hill Rise, Richmond, Surrey.

HOUGHTONS v BUTCHERS.—The football match between the teams of Messrs. Houghtons Ltd. and Messrs. W. Butcher and Sons Ltd., took place on Saturday last at Messrs. Butchers' ground, Highams Park. The game resulted in a victory for the "Enslaved" team (Messrs. Houghtons Ltd.) by two goals to nil.

ROYAL ZOOLOGICAL SOCIETY OF IRELAND.—In the recent photographic competition instituted by the above society, the silver medal for the four best pictures taken in the Gardens was awarded to Mrs. Helena C. Sutherland of Clogheen, and the bronze medal was open to amateurs under the age of eighteen, was gained by John H. C. Gainford, of Bray. It is hoped that next year there will be a larger number of competitors, especially in the bronze medal class, the winners in which obtain a number of free admissions during the year.

## Commercial & Legal Intelligence.

**A SURBITON BANKRUPT.**—Alfred Augustus Woodward, director of a public company, and photographic postcard dealer, of Effingham Road, Surbiton, and lately carrying on business as a photographic postcard dealer at Clacton-on-Sea. At the first meeting of the creditors interested under this failure it appeared that the receiving order was made on November 5 on the petition of a creditor, and the Official Receiver stated that the debtor had not yet filed his statement of affairs. The debtor claimed to hold the lease of a shop at Clacton-on-Sea, under which he could close up the shop in the winter and re-open it in the summer months, but whatever interest the debtor had in the lease would pass to the trustee under the bankruptcy. If it was found that there was a goodwill attached to the shop the trustee would have no difficulty in disposing of the lease. He had requested the debtor to file certain accounts, and if the creditors decided to adjourn the meeting he would no doubt be able to give them further information at the adjourned meeting. After further discussion it was decided to adjourn the meeting for a week.

**A BOSCOMBE BANKRUPTCY.**—John Harris, of 75, Haviland Road, Boscombe, where he carries on the business of a photographer, was examined in the Poole Bankruptcy Court last week. His gross liabilities were £107 14s. 3d., and there were no assets. His cause of failure was stated to be "transactions with moneylenders." The debtor acknowledged that he had had a rather varied career. He had been in a mineral water factory, a brush factory, a hosier's assistant, employed with his father in a brewery at Kingston-upon-Thames, a hotel-keeper, then a traveller in sewing machines, watches and Bibles, and finally a photographer. His photographic business did not pay, and he had recourse to moneylenders, and this proved to be the first step to bankruptcy. He was forced to borrow, partly in order to meet liability in regard to a mortgage, judgment having been obtained against him for £85 14s., with costs. The debtor was allowed to pass.

**CAMPBELL-GRAY, LTD. (PHOTOGRAPHERS, LONDON).**—Issue on November 7 of £350 6 per cent. debentures, part of a series created same date, to secure £1,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees.

**THE CERIO PHOTO CO.**—At a general meeting of the Cerio Photo Printing Company, Ltd., held last week at their offices in Great Winchester Street, E.C., resolutions were passed to voluntarily wind up the company. Mr. P. W. Strauss has been appointed liquidator.

**A RECEIVING ORDER** has been made in the case of Harry Flach, photograph dealer, etc., 235, Cricklewood Broadway, formerly known as 9, Chaddesden Parade, High Road Cricklewood. The first meeting of creditors is to be held on December 6, and the public examination is fixed for January 23.

### NEW COMPANIES.

**HATTON PRESS.**—Capital, £2,000 (£1). To take over (1) the "British Optical and Photographic Trade Journal" and the "Optical Almanac," carried on by T. B. Sewell, at Temple House, Temple Avenue, E.C., and elsewhere; and (2) the "Optician and Photographic Trades Review," carried on by the Gutenberg Press, Ltd., at 123-5, Fleet Street, E.C. Agreements (a) with Colonel T. B. Sewell and (b) with the Gutenberg Press, Ltd., and C. Hyatt Woolf. No initial public issue. First directors—Colonel T. B. Sewell (chairman) and C. Hyatt Woolf (both permanent, subject to each holding 500 of shares allotted to him under purchase agreement). No remuneration for first directors. Qualification (except first directors or successors nominated by them), £100. 123-5 Fleet Street, E.C.

**DANIELL BROS., LTD.**—This company has been registered with a capital of £1,500 in £1 shares. The objects of the company are to take over the business of photographers, etc., now carried on at 38, Morley Road, Lewisham, S.E., under the style of Daniell Bros. The company has been registered without articles of association, and there will be no initial public issue.

## News and Notes.

**THE HEPWORTH CINEMATOPHOTOGRAPH FACTORY**, Walton-on-Thames, was considerably damaged by fire last week, and one of the employees, a lad named Lane, was burned to death.

**THE WARNER-POWRIE PROCESS AT THE R.P.S.**—On Tuesday in next week, December 3, Mr. John H. Powrie is to lecture on the "Florence Heliochromic Plate," that is, the linear screen-plate which is the basis of the Warner-Powrie process.

**WORTHING CAMERA CLUB.**—The annual exhibition is fixed for March 9, 10, 11, and 12, 1908. Entries close February 29. Exhibits should be delivered on Friday, March 6. There will be the usual open and club classes. The hon. secretary is Mr. Edmund F. H. Crouch, 11, South Street, Worthing.

**50s. ANASTIGMATS.**—Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C., ask us to notify that their special offer of the "Nulli Secundus" lens at reduced prices closes positively at the end of the month. To those ordering from abroad the lens will be sent at the present price in the case of all orders received up to December 31.

**£10 FOR A PHOTOGRAPH.**—A sum of £10 is offered for a suitable advertisement photograph by the proprietors of the "Eudes Carnes" cordial. Particulars of the firm's offer appear in our advertisement pages, from which it will be seen that photographs can be received up to January 1 next. We gather that it is the aim of the proprietors to get a photograph which need not necessarily be of a kind suitable for direct reproduction as an advertisement, but must possess an advertising idea, which may be worked up in other forms. This is not to say, of course, that technical excellence of the photograph is any drawback.

**THE RIGHT TO THE PORTRAIT.**—A curious case hinging upon French law as to divorce came before a Paris court last week. A shopkeeper, in a divorce case, learnt that a photograph of his child, confided to the care of the mother, had been reproduced on postcards. He immediately instituted legal proceedings against the photographer and the publisher of the postcards. His argument was that the fact that his child was confided to his wife did not deprive him of his paternal rights. Notwithstanding the authorisation given to the photographer and the publisher by the mother, he was opposed to the child's portrait being reproduced. The Court found that the father had not lost his paternal power over the child, and forbade the photographer and publisher from putting into circulation postcards bearing the child's portrait, under a fine of 10 francs for each infringement.

**ATTEMPTED SUICIDE.**—Mr. G. W. Eastoe, of Caistor, was charged at the local police-court last week with attempted suicide. Dr. Gaman found the prisoner in a state of collapse, and stated that he was distinctly sane, but suffering from mental strain. On being charged, the prisoner said all he could recollect was feeling compelled to do it, that it was an act of remorse brought on by trouble, and expressed his sorrow. He was committed for trial at the next quarter sessions, bail being refused, as in the opinion of the doctors it would be unsafe.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—The usual quarterly dividends of  $1\frac{1}{2}$  per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of  $2\frac{1}{2}$  per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock of the Eastman Kodak Company of New Jersey, will be paid on January 1, 1908, to stockholders of record on November 30, 1907. Cable advice has been received that, in addition to the usual quarterly dividends payable January 1, an extra dividend of 5 per cent. upon the common stock has been declared, payable on February 1 to shareholders of record on November 30.

**MAGIC MIRROR EFFECTS.**—Mr. Douglas Carnegie writes to "Nature":—"I had occasion recently to coat with collodion a silver surface mirror on patent plate 2 millimetres thick. During the operation the mirror was held with one of the rubber pneu-

matic holders frequently used by photographers when coating or varnishing plates. As the film of collodion set, a series of interference colours disposed in concentric circles appeared immediately over the region of the suction disc or the holder. I could scarcely bring myself to encourage the idea which at once occurred to me, viz., that the slight suction of the pneumatic holder was actually deforming so thick a plate of glass and producing an appreciable concavity in its vicinity.

But this seems really to have been the case. For when the beam of light from a lantern (placed with its back to the screen) was reflected back on to the screen by the mirror held with the pneumatic holder, there appeared in the rectangular patch of light determined by the size and shape of the mirror a much brighter internal circular patch which changed its position conformably with any alteration of the position of the pneumatic holder.

I have never seen any reference made to deformations produced in this way; yet such deformations might be found to have a practical significance in critical coating operations where absolute uniformity in the thickness of the coating is desired.

**MR. STEICHEN ON AUTOCHROME.**—To the announcement of the forthcoming appearance of the number of "Camera Work" to deal with the new Autochrome process we should add that the text will be from the pen of Mr. Edouard Steichen, to whom is due the modification of the procedure which has been adopted by other American workers.

**THE HOUGHTON SMOKER.**—Houghtons Ltd.'s annual "smoker" takes place on December 20, in the Georgian Hall, Gaiety Restaurant. A fine array of professional talent has been engaged.

**COLOUR-PHOTOGRAPHY DEMONSTRATION.**—The Central Photographic Society have arranged for the delivery of two popular lectures (illustrated by lantern slides and practical demonstrations) on the subject of "Colour Photography," by Mr. Henry J. Comley, of Stroud, Glos., on Friday, December 13 and 20 next, at 7.30 p.m., at 346, Strand (new "Morning Post" building). Full particulars may be obtained on application to Mr. Hobday at the above address.

**A PHOTOGRAPH WHICH WILL BECOME HISTORIC.**—The Boardman Electrical Patents Company, Ltd., writes:—"It will doubtless be of interest to many of your readers, and particularly so to upwards of 400 of our professional customers to know that the (reflected rays) open arc lamp apparatus that was used when the five Queens and three Kings were photographed together at Windsor Castle a few days ago was one of our triple pair carbon open arc lamps and reflector that we supplied to Messrs. W. and D. Downey, Court photographers, of Ebury Street, W., some six years ago. The carbons were taking 60 volts across each pair, and the current was 30 amperes thus producing a light of 10,000 candle power, and we hear that the exposure was instantaneous."

**MR. JAMES KERR**, photographer, of Swan Park, Monaghan, died suddenly on the morning of the 24th inst.

**ARTIFICIAL LIGHTING FOR STUDIOS.**—Messrs. O. Sichel and Co. advise us that they have made arrangements to show the working of the mercury-vapour and of the enclosed and open arc lamps at their West-End showrooms, 52, Regent Street (near Piccadilly Circus). Messrs. Sichel will be pleased for intending purchasers to bring their own plates and test the lamps on the spot. Messrs. Marion and Co., Ltd., also notify us that they have fitted Schottmercury-vapour lamp in their showroom at 22-23, Soho Square, and will be pleased to show the working to customers at any time.

**PROFESSIONAL ACCESSORIES.**—A catalogue which may be commended to the professional photographer is that newly issued by the Billcliff Camera Works, Richmond Street, Boundary Lane, Manchester. It contains specifications and particulars of studio cameras and stands, of a variety of repeating backs for midget works, a specialty of the firm, together with descriptions of other apparatus which are of special service to the business photographer. Among these may be mentioned the rapid bromide printing frame and printing table, the Billcliff enlarger, a moon accessory and incandescent gas installations for portraiture. The catalogue will be sent free on application.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### INFRINGEMENT OF COPYRIGHT.

To the Editors.

Gentlemen,—There is one subject which almost invariably crops up in your answers to correspondents every week, that of copyright. In most cases your enquirers seem to have had their photographs pirated, and they ask your advice as to how to tackle the pirates. You generally say, "Go for 'em," but those of us who would like to see the fight between the robbed and the robber never do so. Is it that those who have had their photographs pirated have no courage to "go for" the pirates, or is it that they have no faith in the law of the land? This law says plainly that anyone who repeats copies, colourably imitates, exhibits, etc., etc., any repetition, copy imitation, etc., of a copyright photograph shall forfeit to the proprietor of the copyright a sum not exceeding ten pounds. That is ten pounds or less for each copy made, or sold, or exhibited.

Judging from the number of photographers who write you, Sir, each week, there must be at least fifty piracies in each year, yet how rarely do we ever hear that any of these pirates are "had up" for breaking the law.

You would not advise those who have suffered from piracy to take action if you did not think it would pay. It would be most interesting to most of us who have suffered in this way if we could learn what success your correspondents have had in getting the butter out of the dogs' throats.

My own experience in fighting these rogues is that it does not pay. Even if one wins one's case one has to prove to the Judge's satisfaction how much pecuniary loss the identical piracy has caused us; this is, of course, an impossible thing to do. Even if the Judge thinks he will be generous and gives an award of £10, this sum never has yet paid the out-of-pocket expenses.

Solicitors who have had any experience with copyright actions know what poor consolation the victims ever get, and always advise their clients to "grin and bide it" rather than fight.

There must be many photographers who have had their photographs pirated by postcard publishers in all parts of Britain, and they would, I am sure, be glad to fight the pirates if they could only find a Judge who would be willing to award even £1 for each pirated copy sold, but, and a big but too, where is the Judge who would award a photographer £1 for each copy pirated? A photographer may spend the best part of his life in making a few good photographs, and any postcard publisher may reap the benefit from these instead of the photographer himself.

I may add that although the Copyright Act of 1862 says plainly that a "colourable imitation" is a piracy, yet I have lost more than one case because a few unimportant details had been altered in the pirated copies.

One thing also puzzles me. Is it compounding a felony to accept so much from a pirate to hush a case up and say no more about it? In last week's "B.J." you advised a sufferer to ask £1 ls. from a pirate if he, the pirate, sold his stolen goods for a penny, or £2 2s. if he sold them for 2d.—Yours obediently, F. M. SUTCLIFFE.

25, Skinner Street, Whitby, Yorks.

November 20, 1907.

**P.S.**—The poor tramp who steals a pennyworth of bread from a rich baker gets far more than a pennyworth of punishment. Why should the rich publisher who steals a photograph from a poor photographer be let off without any punishment at all?

[Our usual advice has been to square matters with the infringers out of court, as instance the reply quoted by our correspondent in his last paragraph. The double-rate charge for unauthorised reproduction is adopted, to our knowledge, by photographers making a special business of reproduction rights. Our correspondent ignores the fact that the penalty of at least one coin of the realm (a farthing)

every infringing copy has been set aside by several judgments, notably those of "Nichols v. Parker" ("B.J." May 17, 1901, p. 312) and "Hildesheimer v. Faulkner" ("Times" Law Reports, 1901, 757).—Ens, "B.J."]

## THE ULTRA-VIOLET RADIATION OF ELECTRIC LAMPS.

To the Editors.

Gentlemen,—In the abstract of Baron A. von Hübl's paper, in your issue of November 22, it is stated that "the mercury vapour (lamp) extremely rich in ultra-violet rays, but in practical work the latter of very little value." I presume that the latter portion of the said sentence is intended to signify that the glass walls of the lamp absorb the greater part of the ultra-violet radiation.

In a previous paper, November 15, von Hübl, treating of the enclosed arc, states that "the glass cylinder surrounding the lamp absorbs the greater part of the ultra-violet rays."

Assuming that the mercury-vapour lamp is intrinsically richer in ultra-violet radiation than the enclosed arc, and assuming what I assume is generally true, that the thickness of the glass of the mercury lamp is less than the thickness of the glass cylinder of the enclosed arc, one would anticipate a richer emergent ultra-violet radiation from the mercury lamp than from the enclosed arc lamp.

I have been recently in communication with Mr. Arthur Payne on the subject of fluorescence, and Mr. Payne sent me the other day a secret message, consisting of a printed paper in which certain words conveying the message were underlined with an invisible ink of quinine citrate. The underlining was brilliantly apparent on the sheet of print was examined in the light of an enclosed arc lamp, but absolutely no indication of the underlining could be detected in the light of a mercury-vapour lamp. Yet from all I had read concerning the richness of ultra-violet rays in the mercury-vapour light I anticipated a very brilliant fluorescence of the quinine markings in this light. Can it have been that the greenish-blue fluorescence there but not apparent, owing to lack of contrast due to the lack of greenish-blue illumination dispensed by the lamp?

Blackheath, London, S.E.

DOUGLAS CARNEGIE.

November 25, 1907.

## PORTRAITURE BY ARTIFICIAL LIGHT.

To the Editors.

Gentlemen,—It may be interesting to you to know that since the Artificial Light Exhibition opened I have been visited by five well known photographers from all over the North of England, to each whom I have demonstrated the mercury-vapour lamps, as used for portraiture. I have also answered a number of letters from persons from over England and Scotland, dealing with questions arising from the article on the mercury-vapour lamps, in the "B.J." of last week. I think it is only right that you should know that your article has been so greatly appreciated, and I hope you will attain the same success in your other articles. Yours very sincerely,

GEO. R. HENDERSON.

2, Elliston Street, Hebburn-on-Tyne.

November 25, 1907

## DRYING OF OIL PRINTS DURING PIGMENTING.

To the Editors.

Gentlemen,—The matter of the temperature of the external air during the pigmenting of the image in the oil process has been dealt with both by Mr. Rawlins and myself, in our communications on the subject. It has an effect, not only in the drying of the print, but on the viscosity of the pigment, in each case tending to give flat prints as it rises above 60 deg. F. I find that to prevent the print drying too quickly whilst pigmenting, it is a good plan to first lay the plate glass basis two layers of old clean linen, then over two pieces of white blotting-paper. The blotting-paper should be used more than three times, as frequent wettings have the effect of making it to be less porous; doubtless also the "dabbing" has some effect on this loss of porosity. The tendency of the pigment to the too thin can be obviated by allowing some of the excipient to evaporate, after it is spread on the palette, and before charging the brush.—I am, yours truly,

A. R. F. EVERSHEED.

Harley Street, Cavendish Square, W.

November 25, 1907.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. C. Harrison, 69, Southtown, Great Yarmouth. Photograph of River Steamer "Tilly," lying at Burch Castle Great Yarmouth.

R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Six Photographs of Model of Steam Ship "Maurelania."

L. W.—We should say the print is on a matt collodion paper, toned with gold and platinum, but some of the dead matt gaslight papers come very near to the same effect. We should not call the paper at all a suitable one for the negative.

COLOURED PICTURES.—Would you kindly inform me the best way to avoid the following? After having coloured a portrait in water-colours on rough platinotype paper, with the light on the picture from over the left shoulder, when reversed the work on it shows the touches of the brush, whereas in the other light it looks more even and smooth. Customers often judge their photographs from the reverse light. Do you think the above would be due to the roughness of the paper?—COLOUR.

As a rule, most pictures look best when they are illuminated from the same direction as that in which they were painted. This would be more palpable with those on a rough surface than with those on a smooth one.

GUM COLOURS.—Can you inform me where I can obtain "gum paint"? C. HILL.

We scarcely know what you mean by "gum paint." With all water colours the pigment is ground up with a solution of gum. The moist water colours are ground with a solution of gum and glycerine; the latter is to preserve the colours in the moist condition. Of course, these colours are sold by all dealers in artists' materials, and also by most stationers.

GRAINING ZINC.—I should be glad if you could favour me with the following information—viz., to make a dead matt surface on sheets of zinc, which are used for purposes of the dry-mounting process.—DOGGIE.

The usual method of graining zinc is to wet the plate, dust it over with graining sand, such as is used for graining lithographic stones, and then grind with a piece of thick plate glass or a piece of litho stone, until a smooth and even surface is obtained.

J. L. ZADIK (Johannesburg).—The Schroeder lamp and powder obtainable from Fallowfield, 146, Charing Cross Road, London, W.C., or other London dealers.

MILDEWED LANTERN SLIDES.—I made some lantern slides some time since. On inspecting some of them recently I observed what appears like spots of mildew or fungi, though they are sealed up at edges in usual way, and have been kept in a fairly dry place. Do you think if new ones were treated with formalin before finally dried it would prevent this? One could understand it better if they had been exposed, as gelatine is so hygroscopic.—ALPHA.

Undoubtedly it would, as the gelatine is rendered less absorbent of moisture, and retains some proportion of the antiseptic formaldehyde.

ENLARGEMENT SPEED NUMBERS.—Is there any way of converting the density of negatives, as found from Dawson's densitometer to

Watkins' method, as given in his "Manual," third edition, page 53, and vice-versa? If so, what is the calculation and how made?—J. H. STRODDART.

We know of no conversion rule.

J. H.—(1) The title in the case of the card you send is evidently written in Indian ink or "photopake," on the negative with a fine brush. (2) The card appears to have received a baryta coating.

P.O.P. AT NIGHT.—Will you kindly let me know if P.O.P. prints can be made by artificial light? Electricity is not available. I believe there is some way also of partially printing and then developing. Does this give equally good results? How is it done? Is there any paper which prints in artificial light and gives as good results as P.O.P., and with the purple tone of these?—THE ABBOT.

Except electric enclosed arc or mercury-vapour there is no satisfactory means of fully printing out by artificial light. By using the development process, incandescent gas or magnesium ribbon can be employed, but the process of taking off a fair number of prints will be rather slow. The results, if toned after development, are equal to those by printing-out. Formulae for the developers are given on page 817 of the 1908 "Almanac." A fairly good imitation of P.O.P. is a bromide print toned by hypo-alum. See "Almanac," 1908, p. 825.

FORMULA WANTED.—Could you give me a formula for reducing toned bromide prints (ferricyanide and sulphide)?—PUZZLED.

One method of reducing is to treat prints in the usual way, in the hypo-alum bath. About the best reducer is a mixture of equal parts of copper chloride solution (5 per cent.) and salt (15 per cent.). See the "Almanac," 1908, p. 652.

J. W. PICKERING.—The paragraph should read: "A 2-inch head, with a 16-inch lens, will require a longer exposure than a 2-inch head with a 10-inch lens, because of the greater distance from sitter to lens."

YELLOW BROMIDE.—The whites of some of my bromide prints (done within a year) are yellowish tinge. What is the fault in working? My procedure is to develop with metol-hydroquinone or metol, place in plain hypo bath for 15 minutes at least, give six changes of water, place in alum solution a few moments, then wash for an hour or two in running water, but without as many hand changes as I should like. I do not use any clearing bath. Hypo bath is 12 ozs. of hypo to 60 ozs. water, often only 50 ozs. of water. Alum bath also is variable in strength.—BROMIDE.

Stain is probably due to not washing out developer before fixing. You should always wash after hydroquinone, and use an acid fixing bath for preference.

CALCIUM CHLORIDE COMPOUND.—May I ask you to give me some information as follows? What amount of asbestos is used (say per lb.) with the calcium chloride in making the tablets used in the tubes containing platinum paper to attract the damp? Also what quality of calcium chloride is used? Do you know of any manufacturers of this compound?—PERCY S. DOUGHTY.

The more calcium chloride you can use the better. We have made the compound by mixing calcium chloride with hot water to a saturated solution, soaking the asbestos in the liquid and drying on a stove. We know of no firm which manufactures the compound.

SCREEN-PLATE PROCESSES.—I should be much obliged if you will inform me, through your "Correspondents" column, as to the date of the first patent application (presumably in Germany) for the Krayn screen-plate colour process, and also the number and date of the British patent for same.—SCREEN-PLATE.

The date (of sealing) of the German patent (No. 167,232) is September 24, 1904. The dates (of application) of the British patents are September 22, 1905, and January 25, 1906.

REFLECTOR FOR ENLARGING.—I shall esteem it a great favour if you will tell me if a reflector can be used instead of a plano-convex condenser for enlarging. I have made an enlarging box for 5 x 4 negatives, lighted by two incandescent gas burners, but do not get equal illumination, as I have not been able to

afford a condenser. I have tried ground glass, and tried paper in front of the lights, but still they show when covered the screen. If a reflector would answer can you tell me what they are procurable?—A. SMITH.

J. Lancaster and Son, Birmingham, make apparatus suitable for your purpose.

ENLARGEMENT QUERIES.—1. What strength of an incandescent light is required for making enlargements? 2. What class of lens do you recommend, also condenser? 3. Please describe how to discover a "good" from a "bad" condenser when chasing. 4. Please state names and prices of books on enlarging by artificial light, etc., also working up enlargements in black and white and colouring.—ECCLES.

1. For small work, say 15 x 12 from thin negatives, incandescent gas of, say, 50 to 60 candle power is sufficient. The highest power burner sold by the gasfitters will answer for description. For enlarging to greater dimensions, and negatives which may be hard and dense, a more powerful penetrating light, such as the "Sol" incandescent or similar light, is necessary; for commercial work an arc, best of enclosed pattern, is practically essential. For very weak negatives a professional enlarger will use an oil lamp for best results. 2. A good anastigmat is advisable, but for this, a rectilinear of good quality will serve excellently. Use long a focus as your space will permit. If using arc light, not use a lens with vulcanite or celluloid iris, as the heat will probably destroy it. With incandescent gas it will be safe. The usual double condenser of two plano-convex lenses is commonly used. 3. You can do little more than note colour of glass, regular form of surface, and freedom from striae. The glass should be clear and not green in colour. 4. "Brook's Enlarging," by S. H. Fry (6d.); "Photographic Enlargements," by G. Wheeler (1s.); "Retouching Negatives and Photographs," by Robert Johnson (2s.).

SYDNEY H. CARR.—You need not take the lens into consideration but the light-filter should be adjusted to suit the plate. Messrs. Sanger Shepherd or Messrs. Wratten and Wainwright can advise for this for you. It is important for you to have the best of qualities. We would suggest "optical flats" for the glass and the filters. A graduated filter will have no particular advantage for your purpose.

REMOVING PAINT FROM PHOTOGRAPH.—Can you please inform me whether, and how, I can remove the oil painting from a photograph, probably an enlargement about twenty-five years old. The likeness was lost when the paint was put on, and if it could be removed without spoiling the photograph the picture would be of far more value than at present. Thanking you in anticipation.—CHARLES MARSHALL.

We do not think that, by any means, you will succeed in removing the paint without injuring the photograph. As long as a time the oil in the paint will have become thoroughly oxidised. The only thing we can suggest is that you try the effect of benzol on a small portion of the picture and see what it acts.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The "British Journal Almanac," 1903.—At the time of going to press, 24,782 copies of the total edition of 25,000 have been sold. The remaining 218 copies will probably be in the hands of the trade by the time these lines appear.

Mr. Alexander Mackie, in an article on "Stand Development," page 919, takes exception to recent dicta of Messrs. Wratten and Wainwright, and supports this method of developing as economical, satisfying practical conditions, and sufficiently free from unavoidable drawbacks.

The Autochrome Pyro Developer.—MM. Lumière and Seyewetz have found that a quite small proportion of sodium bisulphite is as good a preservative as any for the Autochrome solution A, which they recommend to be made with water in place of alcohol. (P. 920.)

The Warner-Powrie process came before the R.P.S. on Tuesday evening last. (P. 928.)

We regret to announce the death of Mr. Martin Jacolette. (P. 929.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

The present issue concludes the volume of the "Colour-Photography" Supplement. The index will appear with the "British Journal" of December 27.

Signor Achille Cararra, of Messina, sends us the results of experiments in preparing a non-screen panchromatic plate by the bathing method. (P. 89.)

MM. A. and L. Lumière and A. Seyewetz on the control of Autochrome plates during development. We publish the full text of the paper a brief abstract of which appeared in our issue of a fortnight ago. (P. 90.)

A note by M. Wallon on when to intensify an Autochrome, by M. Gravier on a three-solution Autochrome outfit, and on spectrum tests for over and under exposure of Autochromes appear on page 93.

The Krayn Screen-plate.—Information gathered from the current German journals appears on page 93.

A German patent has been granted to still another screen-plate process. (P. 94.)

A note written after witnessing a performance of colour cinematography by Mr. G. A. Smith, of the Urban Co., appears on page 94.

The "Patents Chronology" commenced twelve months ago concludes in the present issue of the "Colour Photography" Supplement. (P. 95.)

## EX CATHEDRA.

### Even Illumination in Printing.

A writer in the "Photographic Times" has evolved a somewhat new theory with regard to the best method of obtaining even illumination when printing from a negative. Considering that the plate is not evenly illuminated in the camera owing to the obliquity of the light near the margins, and to the cutting off of light by the lens mount, etc., he argues that a negative is, of necessity, denser at the centre than at the edges, and, therefore, that we should endeavour to counteract this want of uniformity by printing with a small illuminant placed approximately at the focal length of the lens from the plate, or a little less. At first sight this seems a very plausible argument. The margins of the plate often receive less than half the light that reaches the centre of the plate, and therefore the rest of the argument seems to follow quite naturally. But if we look at a number of negatives made under these conditions, we shall see very little evidence of this uneven illumination, and if we print from them with a small light as suggested, we shall probably get a print showing a vignettèd effect. The fact seems to be that the writer referred to is treating the matter from a purely optical standpoint, and is neglecting the chemical effects of exposure and the practical methods of exposure. Even though it is true that the illumination of the plate falls off rapidly from the centre to the margins, this effect will not be apparent unless we expose in such a manner as to record it. If the exposure in the centre is just "correct," the falling off will be recorded by decided under-exposure effects everywhere excepting just at the centre, in which case we shall certainly consider the whole to be under-exposed. If, however, we increase the exposure, then, in accordance with the photo-chemical laws governing exposure, the gradation from the centre to the margins will be flattened and the differences will become invisible. Another point that this writer seems to have overlooked is the fact that the deposit forming the negative image will transmit a larger proportion of direct than of oblique light. The light from the lens has not to pass through a scattering medium before it reaches the sensitive surface, whereas that from the light used for printing has to do so, which fact introduces a factor that our writer does not seem to have considered.

\* \* \*

### A Stereoscopic Reflex Telephot.

We recently had the opportunity of inspecting a unique camera of the reflex type manufactured to the special order of that most accomplished photographer of scenery, Mr. H. G. Ponting, F.R.G.S. The camera is provided with a pair of lenses of 24 inches focus, but by twice turning the beam of rays back at a small angle to itself the distance between lens and plate is reduced to one-third the "back focus" of the lens. This is done by interposing two mirrors in the path of the rays from each

lens, and thus securing large images of distant objects at a short camera extension, and without sacrificing the rapidity of the lens. As thus made by the Vegea Société in Geneva, cameras of this description have been in use for some year or two, but the model we have examined is, we believe, the first in which reflex focussing has been introduced. The separation of the lenses is 12 inches, and by adjustment of the mirrors any necessary registration of the two stereoscopic pictures can be done most conveniently while focussing. Such an apparatus, if as beautifully made as the instrument we have seen, is most useful for obtaining striking stereoscopic photographs of subjects, a clear view of which can be had from a distant standpoint. For topographical purposes it can often be of the greatest service.

\* \* \*

#### Exposure with Autochromes.

We see from "Photography" that Mr. Child Bayley has made some experiments on exposure that fully confirm previous statements of our own with regard to the uncertainty that prevails when dealing with variable conditions of light. In our little book, "Colour Photography," in which we had the advantage of collaborating with Mr. Welborne Piper, it was pointed out that, while in bright sunlight even a very little over-exposure was a thing to be avoided, and it was better to err on the side of under-exposure, yet later in the day and in the shade under-exposure was a most important thing to avoid. In speaking of under- and over-exposure we were, of course, considering a "correct" exposure to be that indicated by the meter, but it was quite obvious that in the circumstances the meter could not be giving a correct reading. Our experience was that the meter was only reliable, even in the summer, during a few hours of the day, and with a certain limited class of subjects. If exposure thus varies with the changes of light that take place in the course of the day we must expect similar variations to occur as the season alters, and this we find to be most distinctly the case. Mr. Bayley considers that at this time of the year a speed of Watkins 1 is more nearly correct than a speed of 2 for outdoor subjects. If anything, this probably understates the difference, for we have noted bigger variations than this in a single day.

\* \* \*

#### Half-tones By Wire.

The "Matin" reports that Mr. Pascal Berjonneau, an engineer, has succeeded in transmitting half-tone images by wire. Little detail is given, it only being stated that a Morse instrument is used, and that it can be adapted either as receiver or transmitter. It is not necessary to work on telephone lines, as very feeble currents suffice. A reproduction of the facade of the "Matin" Office, said to be made by the process, is given, and it is stated that when certain improvements which Mr. Berjonneau and his co-worker, Mr. Grineaux, are carrying on at their laboratory at Neuilly are complete, experiments will be made on the State telegraph lines.

\* \* \*

#### The Legal Weight of a Photograph.

There are some few consolations in the photographic business after all. One of them came to a photographer the other day on his asking for the committal of a customer who had been photographed but had not paid. The judge asked for evidence of the debtor's means. The photographer therefore exhibited the picture he had taken, showing his recalcitrant sifter clothed in purple and fine linen and surrounded by a numerous progeny. The photograph was admitted as evidence, and an order to pay issued against the defendant, who did not appear.

#### Gold Chromate.

A short paper in the "Chemical Zeitung" for November 27 last (p. 1.) gives the results of some experiments by Dr. N. A. Orlow on the chromate of gold, a compound which may be assumed to have some interest to makers of P.O. ordinary and self-toning. Dr. Orlow finds that perfectly soluble gold chromate can be prepared by the formula  $\text{Au}_2(\text{CrO}_4)_3 \cdot \text{CrO}_3$ . This formula represents first analyses of small quantities of the compound he has given. The chromate was prepared by treating freshly precipitated silver chromate with a solution of gold chloride. An orange-coloured solution results, and on evaporation deposits gold, leaving crystals corresponding to the above formula.

#### A YEAR OF COLOUR PHOTOGRAPHY.

THE personal acquaintance of three-colour photography which photographers have been able to make during the present year, thanks to the Lumière Brothers, has undoubtedly stimulated interest in other processes of colour photography, while there is equally substantial proof that the advent of the Autochrome plate has revived the zeal of many who, but for it, might have transferred their allegiance to some newer form of recreation; and yet again there is also the accession of raw recruits, who, by their first purchase and use of a camera have been made soldiers for the purpose of obtaining records in colour by the direct process. The photographic trade has reason, therefore, to foster these new departures not for what is to be immediately got out of them, but in order to strengthen the conviction that colour photography, divested of its awesome aspect, is to be taken as a matter of course and to be studied and practised like carbon printing, bromide-enlarging. In discharge of this duty the trade has already been helped by one or two of its members who have been quick to perceive the opportunities offered by the manufacturer in the Autochrome process. Other processes, it may be fairly assumed, will be no less prolific in their generation of saleable accessories, and thus colour photography will be given all the representation in the dealers' catalogues which is thought necessary for adequate chaperonage in the eyes of those who, let us suppose, have not seen the twenty-four pages of the "British Journal Almanac" which Messrs. Sanger-Shepherd devote to a price-list of its appliances and materials. But there are other less evident phenomena which press for the day of colour photography, and will, no doubt, much to hasten it. Anyone who peruses the applications for Royal letters patent which are published in our paper week by week must have noticed the large number which relate to colour photography. That many of these are impracticable ideas of enthusiastic visionaries we, who are a few of them before they reach the authorities at Southampton Buildings, are fully aware, but the fact remains that much work is being done in colour processes with commercial aims, and destined—some of it—to commercial success.

Then who shall deny the imminency of colour photography when an ancient and dignified body like the Royal Photographic Society, with nearly sixty years of tradition, gathers its friends and neighbours together and seeks to find how it may best employ the weight of its authority in aiding the progress of colour photography. To class this ancient body with a mere stripling such as the year-old Society of Colour Photographers would be an impertinence, yet the youth with hot enthusiasm has metaphorically taken his coat off and rolled up his sleeve, has made himself known in every quarter of the globe, has held one exhibition, and will hold another in the ear

summer of next year, and under the administration of its hon. secretary promises to grow to a career of usefulness.

One further sign of the growing interest in colour photography may be discerned in the interest taken in the monthly supplement to our own journal under the title of "Colour Photography." It has been our policy to deal in these special pages with whatever seemed deserving of permanent record. At the risk of loading the columns of "Colour Photography" too heavily with matters of historical interest we have published a "Patents Chronology," in which we have given a précis of the British specifications of inventions from the date of the first of these documents until the time (1904-5) when a systematic record of patents is to be found in the "British Journal." This "chronology" is fortunately completed in the present issue of "Colour Photography," and its absence from future issues of the "Supplement" will thus

give us the opportunity of devoting greater space for matter of more immediate practical interest. Still we may feel some satisfaction at having compressed into the first annual volume of the "Supplement" a chronological record of what has been patented, in the way of colour photography, in the United Kingdom, since the first classic application of Du Hauron. We would only add that with the last issue of the year will be issued both the general index to the "Journal" and a separate index to the "Colour Photography" supplement. The latter may thus be separately bound, and may, we hope, rank as a reference volume in colour photography from the fact that to its index will be appended a separate set of references to colour matters in the "Journal." One single consultation will thus refer the reader to all the articles, papers, patents, etc., which have appeared from the office of the "B.J." during the year.

## STAND DEVELOPMENT.

ALTHOUGH the method of developing plates known as Stand Development has been advocated and proclaimed for several years, and experience has shown that the departures from the usual conditions of development which may be made on adopting this method at times give rise to results abnormal, or at least unexpected, it is curious that no systematic inquiry has been made into the causes of the variations that are noticeable. Messrs. Wratten and Wainwright in instituting an investigation into the subject will deserve our thanks, and it is to be hoped that they may be induced to continue these experiments on the same lines but broadening their enquiry.

The paper which was recently published in THE BRITISH JOURNAL OF PHOTOGRAPHY was, I believe, issued originally as a leaflet primarily addressed by Messrs. Wratten to the users of their plates, and presumably their remarks and strictures were intended to be read in connection with the use of those plates. With this limited application, criticism of their precepts would be as much out of place as criticism of the formula they give for the development of their plates on their plate boxes. They make the plates and should know what may and may not be done with them. But as the publication of the paper in the "B.J." and elsewhere as a substantive article causes the publication to be taken as general, no apology is needed for my venturing to differ from them in some of their criticisms and disagreeing with some of their statements.

### A Query as to Extravagance.

The economy of the system is impugned on the ground that the tanks made for the purpose, ingenious and convenient as they are, require a very large quantity of developer." Presumably it is intended to say, they require an unnecessarily large quantity, and it is the fact that the commercial articles generally do. But that goes to prove that the tanks are really neither "ingenious nor economical." The fault is with the tanks therefore, and not attributable to the system. But according to Messrs. Wratten's measurements the quantity employed in "one of the smallest" of the commercial tanks constructed for six half-plates is 29 oz., say 30 oz. to make a round number, and as throughout the paper a solution consisting of a normal developer diluted ten times is given as typical, and therefore the equivalent amount of normal developer for six half-plates would calculate out at 3 oz., it can hardly be conceded that they have made good their case against economy.

### Stand Development, Quick and Slow.

It seems more than possible that Messrs. Wratten have used the expression "Stand Development" in a limited and somewhat misleading sense, without realising that they have done so.

The context of their papers shows that they regard stand development as essentially connected with the use of extremely diluted developer. It does not necessarily mean anything of the kind. The objects of the method of placing the plates upright in a rack are, primarily, two: in order to save the table space required when a number of dishes are used, and in order to prevent the mottling that frequently occurs when plates are developed in dishes without constant rocking. A more dilute developer than usual is generally, but not necessarily, employed, but the precise strength of the developer is very much a matter of personal convenience. A developer that acts too quickly to allow the plates to be removed from the tank without risk of showing a marked difference in the stages of development between the first and the last is naturally not a convenient one, while, on the other hand, a developer that requires an hour or more is likely to cause inconvenience in another direction. Probably the balance of advantage will be found in arranging for development to take from 15 to 30 minutes. This will not involve extreme dilution of the developer, and thus the risk of those troubles arising, which Messrs. Wratten have referred to as incidental to the method of development, will be reduced, and with a really ingeniously designed tank the cost of the developer will still be well under that required with the ordinary tray method. The tank arrangement should preferably be a rack closely fitting into a tank, and so constructed that, while sufficient space was left between the plates, where the developer is required, no unnecessary space is left elsewhere. This arrangement is especially convenient from the facts that the operations of fixing and washing can be carried out without transferring the plates from the rack in which they were held for development, thus minimising the necessity for handling them while wet, and that the plates can be removed from the tank and the developer stirred from time to time if necessary.

### The Unimportance of Stand-Development Irregularities.

It is to be gathered that Messrs. Wratten's deprecatory attitude towards stand development arises from their having approached the subject from a particular point of view, that point of view being that some system of development based upon the calculation of the time occupied is the only desirable or correct method to employ. It is perhaps a natural point of view for the plate maker to take, and it must be conceded that for plate testing it is useful, and in some special applications of photography a time system is the only system possible. But because dilution of the developer upsets or renders more difficult the application of the time it takes to complete development it does not follow that the employment of dilute developer is

either unscientific or undesirable. The majority of photographers do not practise any timing method. They cover their plates with the developer and take them out when, according to their judgment, development has reached the proper stage. In using stand development they do the same. The time occupied is longer. It is purposely arranged to be so, but as in either case time is not a matter of consideration, it is only a matter of convenience and not of necessity to know even approximately how long development will take. It is interesting to learn that the time of development increases out of proportion to the degree of dilution of the developer, and that the proportion further differs with some developers according to the amount of air in the water, but the knowledge of these facts, which seem to Messrs. Wratten to have so important a bearing on the utility of the stand method of development, is really of quite minor importance except from the particular standpoint from which they view the position.

In concluding their paper Messrs. Wratten deal with tank markings and fog, and here they give a lugubrious list of pitfalls to be encountered, and it must be admitted that their list is not complete. There are others they have not alluded to, probably have not met with. But though some of the reasons they give for defects are obviously sound, there are some that are a little far fetched. It is hardly conceivable, for instance, that the air of a dark-room that one could breathe without discomfort could be sufficiently bad to affect appreciably the whole of the solution in a tank, seven or more inches deep, in the space of time that development occupies. That there are certain precautions necessary to be observed in adopting the stand method just as there are in the ordinary method, and that the neglect of observing these precautions under any circumstances is likely to affect results injuriously, is axiomatic. It is well to point out what these precautions are, and in doing so general terms were sufficient, but it was unfortunate that general terms were maintained throughout the papers. To say that the use of pyro-ammonia as the developer will cause green fog as a general statement is not true, but to apply the same statement specifically to a certain plate, or, more broadly, to add, with some plates, alters the position entirely. It is reasonable to suppose that Messrs. Wratten intended their depreciation of the system to apply to its employment with their own plates, but they do not say so. They mention incidentally a particular variety of

their plates, but that is only in connection with time calculations. The omission was probably an oversight, or was though unnecessary in a communication addressed to users of the plates, but its effect is to reduce much of what they say to the level of the general statement concerning pyro-ammonia as above illustrated. That is faulty from want of specific application.

#### A Future for Stand Development.

The plate is a most important factor, and the behaviour of particular plate under conditions of development normal, and the quality of the results thus produced are no guide whatever to what it will do under the modified conditions of stand development. Some good plates behave badly under stand development, especially with extremely diluted developer, just as some good plates behave badly with pyro-ammonia. That it is so does not imply a general condemnation of the plate, but knowledge of the fact broadens out the scope of an enquiry into the theory and practice of stand development immensely. The subject is growing in interest and importance. The convenience of the method in the saving of space, and indirectly of time, when many plates have to be developed, is an advantage which, I venture to prophesy, has only to become better known and appreciated to lead to a revolution in development methods. If, as I contend, the plate is an important, if not the most important, factor, plate makers are equally concerned with plate users in clearing up the difficulties, accounting for the discrepancies that exist and formulating the condition for success. It is, therefore, appropriate that the investigation should be carried out by firm of plate makers, and particularly appropriate that Messrs. Wratten and Wainwright should be that firm. Among the first to take up the commercial manufacture of gelatine plates, not nearly three decades since, when the supremacy of Britain in that branch of industry was unchallenged and unchallengeable, they were accorded at once a leading position among British plate makers, and although the science of plate-making has advanced enormously, and we are assailed on all sides, they maintain their position, and thus put us all under at least a sentimental obligation to them in assisting to keep up our national prestige. They can put us under a direct obligation by continuing their experiments and allowing us to benefit by the results of their investigation.

ALEXANDER MACKIE.

## ON THE ALTERATION AND PRESERVATION OF PYROGALLIC ACID IN SOLUTION.

It is well known to every practical photographer that solutions of pyrogalllic acid in water require to be used as quickly as possible after making, owing to their rapid alteration and development of a brown colour. This coloration, which is evident very soon after the preparation of the solution, is produced more slowly in a solution prepared with boiled water and kept in a hermetically sealed bottle. Hitherto in preserving solutions of pyrogalllic acid additions have been made of considerable quantities of sulphite of soda, together with small proportions of acid to neutralise the alkalinity of the sulphite. This method of preserving pyro solutions, however, can only be employed when the presence of considerable quantities of sulphite of soda is no disadvantage. But in the case, for example, of the development of Autochrome plates with pyrogalllic acid, the sulphite of soda is not admissible, owing to its solvent action on the silver bromide of the film: it would prevent the necessary intensity being obtained on the plates.

Solutions of pyro in alcohol discolour much more slowly than those in water of the same strength, and therefore this

method of preparing the pyro solution has been preferred for the developer of Autochrome plates. Still, the alcohol developer does eventually discolour—at a rate which appears to depend upon the make of the pyrogalllic acid. We have found on leaving both sealed and unsealed bottles of 3 per cent. alcoholic solution of pyro (re-sublimed) of three different manufacturers, that the solutions in bottles which were filled and hermetically sealed discoloured slightly more rapidly than those exposed to the air, a fact for which, up till recently, we were unable to find any explanation. We tried the addition of small quantities of pyro to alcoholic pyrogalllic solutions of small quantities of many other substances, as well as those of a reducing character, in order to prevent this discoloration. These substances had to be used in very small doses, in order to preclude their injurious action on the Autochrome developer. The substance which in small quantities has given us the best result is bisulphite of soda. About one drop of the commercial sodium bisulphite is sufficient to keep bright 100 ccs. of 3 per cent. alcoholic pyrogalllic acid solution of any manufacture.

The results obtained with alcoholic solution have led us

Further experiment with the action of bisulphite on solutions of pyro in water, which latter are, as is well known, much more amenable to alteration. Our experiments have been made on solutions of pyro in water, the strength of which has been from 1 to 50 per cent., to which has been added from one to three drops of commercial sodium bisulphite solution per 100 ccs. of pyro solution. They have been made both in the light and in the dark, and with the employment of both ordinary and distilled water. The following are the conclusions from these experiments:—

1. Solutions of pyrogallic acid in water discolour both in and out of contact with the air, but the discoloration is considerably more rapid in the former case.
2. Light appears to have no appreciable action on the change.
3. Solutions prepared with ordinary water discolour more

rapidly than those in distilled water. In both cases the rapidity of discoloration increases with the strength of the solution.

4. The addition of commercial sodium bisulphite in very small quantity prevents the discoloration of these solutions. The portion of bisulphite necessary decreases with the strength of the pyro solution. For one litre of 3 per cent. pyro solution 1 cc. of bisulphite solution is needed; for the same volume of 50 per cent. pyro solution 2 ccs. of bisulphite are required. The solutions of pyro and bisulphite in water can be conveniently employed in place of the solutions in alcohol for the development of Autochrome plates, as also for almost all other photographic processes.

A. AND L. LUMIERE.  
A. SEYEWETZ.

THE CLASSIFICATION OF PORTRAITS.

[In the following communication to "Nature" Mr. Francis Galton endeavours to establish a method of charting the features of various types of face in such a way as to allow of the classification of portraits of human portraits made by photography, it should be possible, of a formula.—Eds. "B.J."]

EXPERIMENTS of various kinds that I have made to define the facial peculiarities of persons, families, and races by means of measurement led to the following results that seem worthy of publication. The most elementary form of portrait will alone be considered here, namely, the outline of the face from brow to chin, as in a shadow in a silhouette. It contains no sharply defined points whence measurements may be taken, but artificial ones can be determined with fair precision at the intersections of tangents to specified curves. It will be shown that it is easy to "lexiconise" portraits by arranging the measurements between a few pairs of these points in numerical order, on the same principle that words are lexiconised in dictionaries in alphabetical order, and to define facial peculiarities with greater exactness than might have been expected.

The Arithmetic of Beauty.

The individuality of a portrait lies more in the relative positions of its cardinal features (see the figures below) than in the shapes of the

lines that connect them, so long as the general character of the connecting lines is roughly indicated. A few standard types, perhaps ten in all (though I prefer to use more), represent as many concave, convex, and sinuous varieties of outline, between each specified pair of the six cardinal points, as need to be noted. I may recur to this in a future letter.

This will be apparent to the reader's satisfaction if he compares portraits under unfavourable conditions, as through a blurring medium, or out of focus; or, again, if he substitutes connecting links that differ somewhat from the true ones. Consequently my first endeavour was to define accurately six points that should severally be good representatives of the six cardinal features in the outline. These features, the limits of which are vague, are expressed by *italic* letters in Fig. 2, and their representative points by the same letters in capitals in Fig. 3. The features are these:—*c*, the tip of the chin; *u*, the lower, and *u*, the upper lip; *m*, the hollow between the upper

lip and the nose; *n*, the tip of the nose; *f*, the hollow between the nose and the brow. In order to find their respective representative points, proceed as shown in Fig. 2, by drawing (upon tracing paper) a tangent, *YY*, to both *c* and *f*. Then draw a short tangent to *n* parallel to *YY* (accidentally omitted in the Fig.). A tangent to both *c* and *n* intersects the first of these lines at *C* and the second at *N*, and determines them. A line drawn from *N* tangential to *f* determines *F*. Thus the fundamental triangle *CNF* is obtained, in which *YCFY* is used as the axis of *Y*, and the length of *CF* (divided into 100 equal parts, here called "cents") determines the scale of measurement. In the life-sized portrait of an adult, 1 cent may be regarded as roughly equivalent to 1 1/4 mm. or to 1/20th of an inch. *M*, and consequently the triangle *CMN*, is determined by the intersection of one line drawn from *C* with another from *N*, both tangents to *m*. *U* and *L* lie at the intersections of tangents drawn in either case, parallel to *X* and *CN* respectively. They require less attention than the preceding letters, because *u* and *l* are usually small.

The positions of the six cardinal points may be expressed in either of two ways—(1) as in Fig. 3, by rectangular co-ordinates, *YCY* being the axis in *Y*, and *XCX* perpendicular to it, the axis in *X*. Or (2), as in Fig. 4, by triangulation. Here an additional line, *NP*, drawn perpendicularly from *N* to *YCY*, is convenient. I have compared both of these methods, and found each to have its advantages and disadvantages, depending on many variable causes, of which the scale of the portrait is one and the available instrument is another, and am inclined, on the whole, to prefer the methods of co-ordinates.

The Use of Codified Portraiture Criminology.

In my experiments I have chiefly used the side-view portraits, by George Vance, R.A., of his distinguished contemporaries, published in 1809 (two vols., folio, Longmans), which yielded sixty-eight pure profiles of about one-third the natural size. I lexiconised these in respect to the measures (entered to the nearest cm.) of the two co-ordinates of *N* and *M* respectively (4 measures in all), and found, first, that no two of the numerical formulae were the same; and, secondly, that in two-thirds of them the *smallest* difference between the most nearly resembling pairs was 3 cms. in one or more of the four measures. This conspicuous difference, equivalent to between 1/6th and 1/7th of an inch in a portrait of the natural size, could never be due to the inherent imperfection of the art of measurement, but to some gross blunder. It follows that the collection of sixty-eight portraits was lexiconised with remarkable precision. The data were insufficient to enable me to speak with much assurance of the gain that would accrue from taking *L* and *U* into additional account, but their correlations with *C*, *M*, *N*, and *F*, seeming to be very small, the gain ought to be great. I am content to under-rate this gain considerably, and to allow only fifteen-fold for it. On that basis a collection of 1,000 profiles from brow to chin could be lexiconised

and searched with great ease. In 667 cases each portrait would have a clearly distinctive formula; in the remaining 333 there would be doubtful duplicates, and even triplicates, just as in any list of the names of 1,000 British persons there would be more than one Smith.

In the report of a committee appointed by the Secretary of State in 1894 (C.—7,263, price 10d.) to inquire into the best means available for identifying habitual criminals, the following remark appears on p. 18:—"An enormous amount of time is spent in examining the book of photographs. It will be seen from the figures furnished by Chief Inspector Neave that on March 1 last twenty-one officers searched for twenty-seven prisoners—the total time spent being 57½ hours—and made seven identifications. This was an average of more than two hours for each prisoner sought for, and more than eight hours for each identification." A similar search in a lexicon of portraits of the same size would occupy apparently fewer minutes than the above occupied hours.

I will go no further now into the results of my experiments than to say that I have applied the above method to portraits of persons of very different races, and have thus far found it efficient in all of them.

FRANCIS GALTON.

#### ILFORD, LTD.

THE eleventh ordinary general meeting was held December 3 at Winchester House, Colonel Ivor Philipps, M.P., presiding. The chairman stated that the profit on the trading account showed a decrease, compared with the previous year's figures, of about £14,000. Last year, however, the company established a record in their sales, but some of the causes contributing to that result were abnormal, and had not continued. The business had been affected by the unfavourable weather of the past season, and they had also been adversely affected by other circumstances, with the disappearance of which considerably better results might be hoped for in the future. The volume of the company's business continued satisfactory, but the fierce competition and reckless price-cutting seriously reduced the profits. So long as the price-cutting continued, the manufacturer of photographic plates and paper would be unable to make the large profits on his turnover to which the shareholders had been accustomed in the past. If they compared the company's sales of 1903 with those of last year, they found that they were the same within a very small percentage, and yet the additional discounts they had had to concede in 1907 amounted upon the year's turnover to a sum equal to about 10 per cent. on their ordinary share capital. It was also very well known that the trade was more divided up than it was formerly. The directors were not without hope that the price-cutting might be put an end to in the interests of all concerned by means of a proper understanding among the trade itself. He could not hold out any immediate prospect of relief in this respect, but the matter was having the very serious attention of the directors. They were also devoting much thought to effecting economies in the working of the company's factory, and they believed that much could be done in this direction without endangering the efficiency of their manufactures or the quality of their production. They did not take a desponding view of the future. In spite of competition, the company held their own, although at the sacrifice of profits. The turnover was as large as it was when a dividend of 10 per cent. was being paid on the ordinary shares, and every effort was being and would be made to increase the turnover and to hold their present and secure new markets. He afterwards referred to circumstances which had arisen in connection with the termination of the agreement with Mr. E. B. Knobel, the late managing director, who, however, retained his seat as a member of the board, but who had to come up for re-election that day under the articles of association. The articles provided that, unless some one else was elected in the place of a retiring director, the latter continued in office, and in those circumstances the directors would have felt it necessary to submit to the meeting the name of some other gentleman for election in Mr. Knobel's place. They had, however, been unwilling for various reasons to take this course, and Mr. Knobel had expressed his willingness to meet them in the matter by voluntarily retiring if he were re-elected. His re-election, therefore, was to be regarded as only formal. Two of their colleagues had consented to discharge the duties temporarily of

managing directors; the duty was purely honorary, without an extra fee. They were acting rather as a committee of the board to supervise temporarily the daily working of the business. Although Mr. Knobel had ceased to be managing director, no change whatever had been made in the personnel of the factory or in the scientific or commercial staff; and no alteration whatever had been made in the quality of Ilford goods. He concluded by moving the adoption of the report. Mr. A. R. Smith seconded the motion. A long discussion followed, principally in connection with the circumstances which had led to the differences between Mr. Knobel and the directors.

## Exhibitions.

#### LANCASTER PHOTOGRAPHIC SOCIETY.

At the recent exhibition the following awards were made in the open classes by the judge, Dr. C. Thurstan Holland:—

Class A—Landscape, Seascapes, and River Scenery.—C. E. Hewitt, silver plaque, "Flecked with Sunlight" (No. 1); C. E. Hewitt, placed 2nd (medal withheld under rule), "An Essex Homestead" (2); H. Lindoe, bronze plaque, "The Deserted Mill" (15).

Class B—Portraiture and Figure Studies.—C. H. Hewitt, silver plaque, "The Mirror" (35); E. Lee, bronze plaque, "Condemned" (58).

Class C—Architecture, Interior or Exterior.—C. H. Hewitt, silver plaque, "In Canterbury Cathedral" (71); G. J. T. Walford, bronze plaque, "Touched with Sunlight" (81).

Class D—Lantern Slides (sets of four), any Subject.—J. Ludlow, silver plaque, "Winter" (85); G. A. Booth, bronze plaque, "Thrush" (33).

Class E—Postcards (sets of three), any Subject.—Silver plaque (silver medal withheld); J. Maddison, bronze plaque, "Bunch of Currants" (92).

#### SOUTHSEA PHOTOGRAPHIC SOCIETY.

This exhibition was held as usual in the extensive rooms of the society, 5, Pembroke Road, Portsmouth, from November 29 to December 5, and fully sustained its high reputation among the most important exhibitions of the country. The exhibits numbered between 700 and 800, and included a loan collection of some of the best work of our leading photographic artists, among whom are A. Horsley Hinton, Reginald Craigie, Alex. Keighley, F. Hollyer, Arthur Marshall, J. Craig Annan, W. Thomas, F. J. Mortimer, Mrs. Barton, Harold Baker, J. C. S. Mummery, and many others of equal talent.

Mr. H. Snowden Ward acted as judge and the prizes given were silver vases 8in. high.

In the large open class (any subject) the prize-winners were Mr. G. A. Barton, Robert J. Cocks, R. Dührkoop, Dan Dunlop, Oscar Hardee, H. Mortimer Lamb, Arthur Marshall, and Miss Agn. Warburg, all the awards being of equal merit. Messrs. Henry Comley and Alfred Denton received special mention, and the following obtained hon. mention: Miss Gertrude Aitchison, Herbert Bairstow, Bertram Cox, Dr. Grindrod, C. H. Hewitt, E. T. Holding, Harold Jacob, J. B. Johnston, S. G. Kimber, Mrs. Elizabeth Peak, Miss Ambrose Ralli, Miss Hilda Stevenson, H. V. Summons, and Miss Edith Willis.

In Class B (lantern slides) vases were awarded to W. H. Taylor and Ellis Kelsey; special mention to A. L. Watiss and hon. mention to R. Hancock, Victor Morris, and G. J. T. Walford.

In the open class for Hants and Isle of Wight only there were a large number of exhibits, the winning exhibitors being F. A. Swaine and A. W. Ward, hon. mention being given to pictures by Miss Mary Best, Rev. T. A. Cooper, Colonel Johnstone, C. B. Basson, and Louis J. Steele.

In the members' classes this year there were more exhibitors and many more exhibits, and the work was above the standard of previous years.

In the class for framed prints (any subject) the vases were awarded to S. Dawe (two, one of which he did not take, as he preferred to take the one awarded to him in the lantern class, the

rules not allowing one competitor to receive more than two prizes in all), Colonel Johnstone, F. J. Lawton, E. H. Plumpton, L. J. Steele (two), and A. W. Ward (two), special mention being given to pictures by S. Dawe, L. J. Steele (two), and A. W. Ward, and hon. mention to works by M. W. Cliffe, S. Dawe (two), Colonel Johnstone, C.B. (three), Louis J. Steele (six), and A. W. Ward.

In Class E (for those who had not previously won any award), also framed prints (any subject), vases were awarded to A. J. Luke and J. C. Thompson, hon. mention being given to pictures by W. H. Barrell (three), A. J. Luke, and W. Stimson (four).

In the lantern slide class the winners of the vases were S. Dawe and Colonel Johnstone, and hon. mention was given to F. S. Hoyte. The Canning Challenge Shield, presented by Henry A. Canning, Esq., to the exhibitor of the best average work in the members' classes, was won by S. Dawe.

The hon. secretary and the Committee of Management of the Exhibition are very gratified with the success of the exhibition, and are particularly grateful to those who have contributed to the loan collection so many of their valuable works. They are also very gratified with the exhibits sent for competition, which comprise works of the highest standard. The average quality throughout taken collectively is excellent.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between November 18 and 23.

**ELECTRIC LAMPS.**—No. 25,511. Improvements in electric portable photographic lamps. Oscar Thomas Banks, 49, Mortimer Street, London.

**SHUTTERS.**—No. 25,537. Improvements in or connected with roller blinds or shutters. Arthur Wells, 4, South Street, Finsbury, London.

**PRINTING.**—No. 25,730. Improvements in making tones for use in photographic processes. William Charles Masser and William Hudson, Hatfield Street Works, Stamford Street, London.

**REFLEX CAMERAS.**—No. 25,875. Improvements in folding reflex cameras. Herbert Holmes and Houghtons Limited, 88, High Holborn, London.

**CAMERAS.**—No. 25,966. Improvement in photographic cameras. John Kershaw and Charles Henry Watson, 313, High Holborn, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FIXING BATHS.**—No. 25,869, 1906. The claim is for ammonium hyposulphite as a fixing agent for plates and papers. In order to obtain a suitable bath it is not necessary to use pure ammonium hyposulphite itself, but sodium hyposulphite may be dissolved in water to form a fixing bath and then a suitable proportion of an ammonium salt added, such as for instance ammonium chloride or ammonium sulphate. In preparing a fixing bath in this way it is preferable to arrange the bath so that it contains substantially ammonium hyposulphite, but an excess of one of the ingredients may be present.

The improved fixing agent may also be provided in the solid state. For this purpose solid sodium hyposulphite, preferably the desiccated sodium hyposulphite, is mixed with a suitable ammonium salt, such as, for instance, ammonium chloride or ammonium sulphate; in order to obtain the new fixing bath it is then only necessary to dissolve this mixture in a suitable proportion of water.

The new fixing agent has the advantage that when it is used the fixing operation occupies only one-half the time consumed when sodium hyposulphite is used; moreover when several plates are fixed in succession in the same bath the duration of the fixing remains unaltered, whereas in a sodium hyposulphite bath the

duration of the operation becomes much longer after a few plates have been fixed. Again, when the ammonium hyposulphite has been used several times it remains clear and colourless and does not discolour the negatives or cause spots in them.

The following examples illustrate the invention, the parts being by weight:—

1. In order to prepare a fixing bath according to the present invention, 24.8 parts of crystallised sodium hyposulphite are dissolved in 50 parts of water, and, on the other hand, 10.6 parts of ammonium chloride are dissolved in 50 parts of water. These two solutions are mixed together to produce the fixing bath, which is used in the usual manner.

2. A fixing bath showing substantially the same properties as those of 1 is obtained by dissolving together in 100 parts of water, 24.8 parts of crystallised sodium hyposulphite, 5.3 parts of ammonium chloride, and 6.6 parts of ammonium sulphate. This bath affords all the advantages above mentioned.

3. When the improved fixing agent is to be provided in the solid state it may be made as follows, it being of great technical importance that it is not necessary to prepare the pure ammonium hyposulphite, which salt is rather expensive and in the solid state is hygroscopic:—3 parts of desiccated sodium hyposulphite are thoroughly mixed with 2 parts of ammonium chloride; this mixture is preferably incorporated with a small proportion of sodium bisulphite, for instance with 0.3 parts of it, to give the mixture an acid reaction.

When preparing from this rapid fixing salt a fixing bath ready for use, it is only necessary to dissolve the salt in water, for instance 20 parts of the fixing salt may be dissolved in 100 parts of water.

4. As already stated, it is not necessary that the fixing bath should contain substantially ammonium hyposulphite, the technical effect of the present invention being also attained if the fixing bath contains ammonium hyposulphite in addition to sodium hyposulphite. In this case sodium hyposulphite is in excess in comparison with the ammonium salt used as the other ingredient.

For instance, in preparing a fixing-bath or the improved fixing agent in the solid state according to the invention one may proceed as follows:—30 parts of desiccated sodium hyposulphite are thoroughly mixed with 10 parts of ammonium chloride; in order to give this mixture an acid reaction, which is preferable for use, the mixture is incorporated with a small proportion of sodium bisulphite, for instance with two parts of it.

In order to prepare a fixing bath ready for use from the rapid fixing salt thus obtained it is only necessary to dissolve 10 parts of it in 50 parts of water. A. G. Bloxam, for the Actien-Gesellschaft für Anilin-Fabrikation, Berlin.

**MULTIPLE FILMS.**—No. 7,132, 1907. The claim is for roll or flat film, consisting of two parts; one of a colloid mixture and non-actinic in colour and serving as the support of the other, which is transparent and sensitised in the ordinary manner, the two being united by an intermediate soluble layer.

The non-actinic colloid layer consists of gelatine, collodion, cellulose, etc., to which colouring matter of any non-actinic colour, generally black (carbon, India ink, etc., or red aniline dyes, etc.) has been added. It is, moreover, rendered permeable to water by the addition of glycerine, gum, etc. This first layer or film forming the support is prepared by spreading and evaporating the fluid mass on a rigid and smooth surface, for instance, a glass or marble table.

To this first layer is applied in any desired manner some soluble agglutinant such as gum arabic, tragacanth gum, sugar, glucose, etc.; and on the surface thus formed and dried is spread the material constituting the usual photographic film.

This second layer is coated or provided with a positive or negative emulsion, and then, when the whole is perfectly dry, the compound film is stripped from the rigid surface which has been used when preparing the same.

The operations could also be reversed, that is to say, first the sensitive film may be prepared and the opaque film applied to the back of it, either by coating or by causing a sheet of opaque colloid material to adhere to it by means of a soluble agglutinant. The result is the same as before.

The backed film thus obtained can be made in rolls or in film

plates separately, or arranged in packs without it being necessary to use intermediate black paper, either in the one or in the other case.

This double film is sensitive on one face, and non-actinic on the other, so that if several film plates are superposed in a magazine or plate holder, the film plates can be exposed without fear that the light which strikes the first one could reach those which are placed behind it.

The film has also the advantage of completely doing away with halation, and another advantage consists in the possibility of numbering directly the film plates by printing the numbers on the non-actinic colloid layer, instead of on paper bands as formerly.

After the exposure of a roll film or plate of the present construction, it is sufficient to immerse it for a few seconds either in ordinary water or in any suitable aqueous bath. The liquid penetrating through the non-actinic colloid layer, which is permeable, softens and dissolves the agglutinant so that the two portions of the film separate with the least effort, and even under the influence of their own weight. There is then left the ordinary transparent film which can be subjected to all the usual developing and printing operations. A. Lumière et Ses Fils, Lyons, France.

**ENGRAVING ON GLASS PLATES BY PHOTO-SANDBLAST.**—No. 2,291, 1907. The invention consists of a photographic process for transferring designs, etc., to glass or stone for subsequent engraving by sandblast. An elastic gelatine sensitive mass is applied to the surface in a viscous state, rendered uniform in thickness by a wiping instrument, and then exposed to light under the design.

At the edges of the plate, strips are provided so that they project above the surface. After the plate has been levelled, gelatine is poured on the plate, and the excess wiped off. The remaining thin film is then of uniform thickness, and remains adherent to the plate without flowing, and quickly sets. Should the surface of the plate be uneven or even be curved a special tool is used.

The tool (Figs. 1 and 2) consists of a very thin flexible steel blade *a*, corresponding in breadth with the breadth of the plate, secured

in a handle *b*, and provided along its lower edge with a number of projecting teeth *c*, arranged at intervals apart. The latter are preferably formed by thin nickel wires *d*, which are bent so as to embrace the lower edge of the blade *a*, and are secured to another plate *e*, or the like.

On wiping the surface of a plate, which has been covered unequally with a thick film of gelatine, with this tool, the steel blade follows with its teeth all the inequalities of the surface of such plate, and leaves a uniformly thick film of gelatine at all parts of the surface, the thickness of the film corresponding to the length of the teeth. The narrow furrows made in the gelatine by the teeth on passage of the tool immediately close behind them. A film formed in this manner will not flow off even greatly curved surfaces, in view of its adhesion, but dries quickly in a uniform depth on the surface of the plate.

A suitable composition of gelatine is as follows:

Best quality white gelatine .....	100 gms.
Boiled and filtered water .....	500 cc.
White sugar .....	30 gms.
Clarified glycerine .....	30 cc.

This solution, after being heated to 120 degrees Fahr., is mixed with 3 to 5 gms. ammonium bichromate, with the addition of 3 to 5 cc. ammonia. If more bichromate be added, the gelatine

would obstruct the penetration of the light to the base of the film, and, if less, on exposure to light the gelatine would not be sufficiently hardened, so that when subsequently heated with hot water it would wash off.

Assuming the picture contained on an ordinary photographic plate is to be transferred to the gelatine, the exposure is effected in the usual manner. Preferably a photographic plate produced by the wet collodion process is employed. This is laid on the gelatine film. The whole is then exposed to an arc lamp or to sunlight, and afterwards developed in hot water, whereupon the portions not acted upon by the light dissolve down to the base and expose the glass plate. The picture appears in intaglio or in relief in accordance with whether a negative or positive photographic plate has been employed.

The gelatine-covered plate so treated cannot be acted upon by the sandblast for effecting the engraving of the picture immediately after drying, as the remaining gelatine, by reason of its hardness and brittleness, would offer sufficient resistance to the sand for a short time only, and consequently the engraving would not be very deep, and could not be actually carried out. In order to effect this properly, it is necessary for the plate to undergo a further treatment, which consists in the immersion of the dried gelatine picture in a solution composed of one part of gum solution of 1:3, two parts of glycerine (or sugar), in three parts of water, in which the plate remains for half an hour. After the plate has been washed under a rose and has been dried, the gelatine film has become tough and elastic like rubber, and withstands the sandblast.

Not only should it be possible to transfer pictures from photographic plates to the plates to be engraved, but also hand-made drawings and letterpress must be capable of being transferred by the present process. It has been found that none of the inks hitherto used for printing or drawing is sufficiently opaque. With all such, produced by known means, when exposed to electric light, the violet and ultra-violet rays penetrate the ink and a sharply defined gelatine relief is not obtainable.

According to the present invention, for the characters or the drawings, inks are used which, when applied in a thick layer, have the property of absorbing all chemically active rays. These inks, which are preferably composed of two parts of glycerine and three parts of gum arabic, completely saturated with an alcoholic solution of a suitable aniline colour, such as aurantia or spirituous orange red, cannot be used with ordinary transparent tracing papers, as these latter will not absorb the ink. This difficulty is overcome by using tissue paper, which will absorb the ink to a great depth without spreading. The tissue paper is best made transparent by grape sugar.

In order to render the process capable of universal application, it is necessary that from positive drawings or impressions, negatives should be capable of being directly produced, and vice versa, so that such prints can be employed instead of the originals. This is effected by the present invention as follows:—

The drawing or impression is traced with a light blue gum printing ink, dusted over with dextrine and dried. After being dried the paper is stretched in a frame. By means of a spraying device, an alcoholic solution of shellac, saturated with an aniline colour, such as aurantia or spirituous red, is then uniformly applied, this taking but little time, about half a minute for 1 sq. cm. After a lapse of a quarter of an hour, the tracing can be developed in ordinary water. As soon as the water has penetrated from the back to the gum and dextrine, these substances swell and burst the shellac layer and float off, together with the superposed layer of colour. At those portions not covered by gum, the shellac adheres well, and even enters into the tracing paper on turpentine being added. All good transparent commercial tracing papers can be used for making these tracings.

For greater security or strength the tissue paper impressions, and likewise the shellac prints, can be treated with bronze whilst still damp.

The further operation by means of the sandblast, on the plates provided with the gelatine relief, is effected in the usual manner, and can be continued so as to effect the engraving to the desired depth. Johann Heinrich Frez and Ernst Frez, Schaffhausen, Switzerland.

**DEVELOPING ROLL-FILM.**—No. 8,174, 1907. The invention relates to

the employment of the daylight spool of roll-film in the daylight development machines. The claim apparently is for the provision of a leading strip attached to the backing paper. Edward Crawford Davidson, 557, North Broad Street, Elizabeth, Union County, New Jersey, U.S.A.

**NON-SCREEN ORTHOCHROMATIC PLATES.**—No. 25,728, 1906. The inventor proposes to apply a thin coating of wax to the gelatine surface of an orthochromatic plate, and to apply afterwards a colour layer composed somewhat as follows:—

Alcohol 95 per cent. ....	1 dram.
Liquid glucose or glycerine. ....	2 oz.
Aniline colours .....	(about) 6 gr.

It is not stated how the wax coating is to be removed before development, or whether such operation is necessary. Louis Husson, 2,005, Sth. Broad Street, and André Frederick Bornot, 17th and Fairmount Avenue, Philadelphia, U.S.A.

**CINEMATOGRAPHS.**—No. 19,892, 1907. The claim is for a guiding device consisting of a jointed parallelogram fixed by means of axis to the frame of the apparatus at the centres of two parallel sides, thus forming an arrangement capable of movement whilst keeping its sides parallel one to the other so as to form a groove by the two other sides of this parallelogram, and the width of which may vary according to the width of the band, this groove having as axis a line definitely fixed with respect to the apparatus. R. W. James for the Compagnie Generale de Phonographs, Cinematographs et Appareils de Precision, 98, Rue Richelieu, Paris.

**SELF-CAPPING FOCAL-PLANE SHUTTERS.**—No. 28,174, 1906. The claim is for a construction in which the complete exposing blind is made up of two separate portions. One portion of the complete blind is caused to automatically return and cover the aperture of the shutter box, either immediately after making an exposure, or at the time of setting the shutter ready to make a new exposure, the operation of setting being limited to the winding up of one portion only of the complete blind. Walter Frederick Giles, 15, Bulmershe Road, Reading, Berks.

## New Trade Names.

**ILFORD.**—No. 294,706. Photographic dry plates and photographic films included in Class 1. Ilford Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers and films. July 19, 1907.

**ILFORD.**—No. 294,707. Photographic apparatus included in Class 8. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers and films. July 19, 1907.

**ILFORD.**—No. 294,708. Prepared paper for photographic purposes. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers and films. July 19, 1907.

**KINEO.**—No. 296,682. Cinematographic apparatus included in Class 8. Charles Urban, 48, Rupert Street, London, manufacturer. October 1, 1907.

## New Books.

"Trees and Their Life Histories." By Percy Groom. Illustrated by Henry Irving. Pp. 406, 10½ by 9. (London: Cassell and Co.) 25s. nett.

This handsome work of reference is evidently a volume of the greatest value to the forester; it is certainly a convincing demonstration of the utility of the photograph in sharing the task of explanation of a somewhat technical subject. Mr. Irving's illustrations number over 500, and there is scarcely one amongst them that can be called a bad photograph of its subject. Full justice is done to them by the photo-engraver and printer, and the result is a piece of book-making which is very moderately priced by the publishers. As regards its literary contents, the book gives a mass of essential information under the following heads: Behaviour and growth; Germination; Sprouting; Branching; Production and fertilisation of flowers; Protection and dispersal of seeds; The manner in which trees adjust their shapes to various situations;

How they protect vulnerable parts from injury by climate, weather, etc.; How they replace injured parts; How their structure enables them to live in divers situations; Also how to judge the needs of a tree by mere outward inspection. It is written throughout, as far as is consistent with accuracy, in non-technical language, and the introductory portion supplies the information necessary to adapt it for use by readers unacquainted with botany.

## New Apparatus, &c.

The "Ensign" Drying Rack. Made by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

One dodge of the practical printer and postcard maker which is, perhaps, not very widely known is the use of a thin gauze or net, on which the prints, as they come from the wash-water, are laid face down, and on which they very quickly dry without undergoing the deformation which takes place if they are pinned up or dry face upwards on blotters. Some perhaps will scoff at the idea of employing the method for gelatine prints. We can only say, try it, and take the opportunity of testing for the purpose the special fabric and framework supplied by Messrs. Houghtons. The latter is a more open mesh than can be easily bought, and is, moreover, "gassed" (i.e., singed) to rid it of fluff, and chemically treated to remove grease and any other substances which might mark or injure

the prints. The device is certainly a most convenient aid to the drying of prints, as it saves not time only, but space, a large number of the racks being capable of being stacked (horizontally or vertically) where they will get a current of air. The rack is made in three sizes at the following prices:—

1. 17½ by 10½, for 12 quarter-plates, 2s.
2. 27½ by 15½, for 12 half-plates or 20 quarter-plates, 3s.
3. 35½ by 20½, for 20 half-plates, 4s.

The smallest size, 17½ by 10½, is sent out in a neat cardboard box at the above price; the two larger racks are not boxed.

The "Specto" Reflex Camera. Sold by Spiers and Pond, Ltd., Water Lane, Ludgate Hill, London, E.C.

The camera which we have just received for our comments is one on which the management of Messrs. Spiers and Pond's photographic department have been engaged for some time past. It was intended to have been seen at the exhibition of reflex cameras held at the

house of "The British Journal of Photography" in June last, but matters were not sufficiently advanced, and rather than show an instrument with which they were not perfectly satisfied the sponsors (we disclaim any punning aim) let the opportunity pass. Now the "Specto" has been completed for the market, and though the season for the ordinary cheap hand camera has closed, an instrument of the many merits possessed by a well designed and constructed reflex may be assured of an almost equally interested reception at the commencement of winter, inasmuch as it renders possible throughout the dull days practically every description of hand-camera work. Therefore we are encouraged to give prominence to the new reflex, all the more so since it happens to be an instrument of which we can speak in the sincerest commendation.

In the quarter-plate model which we have had under trial, the outside dimensions of the camera are  $6 \times 7 \times 7\frac{1}{4}$  inches, less than those of other reflector cameras which will not do as much as the "Specto." The hood, as shown in the drawing, is held erect by the struted cover-board of the camera; it is 9 inches in height and gives a clear view of the focussing screen. It is, moreover, quickly collapsible, and, further, is instantly detached at its base from the camera, affording a free access to the mirror for dusting and for wiping the ground glass, both, as reflex users know, operations which are constantly needed in regular work. When using a camera in the rain it is necessary to be able to rid the focussing screen of drops of water, or accurate focussing is impossible. This is most quickly and readily done in the case of the "Specto."

The mirror itself, when viewed from the bared cover of the camera, will be seen to have a zig-zag or shrinking movement when passing from the "down" to the "up" position, and vice-versa—that is to say, on its first release it moves slightly backwards, and so "dodges" the lens mount. This movement, it is scarcely necessary to point out, has the merit of permitting a lens of extra short focus to be used in the case of the "Specto" before us of  $5\frac{1}{4}$  inches in focus, according to our measurement of the clearance of the mirror.

The mirror setting lever serves also for the shutter release, and is so adjusted that, except when specially adjusted, it automatically falls back after exposure, shielding the plate; the mirror thus acts as a self-capping shutter. For time exposure, the mechanism has the very convenient feature, which, so far as we know, is not possessed by any other reflex, of allowing two time exposures to be given in quick succession without re-setting the shutter. The movements are:

1. Pressure on lever opens blind, and release of pressure lets mirror fall.
2. Second light pressure raises mirror, and continued pressure closes blind.

Any necessary operations of changing the plate and of focussing can be done between 1 and 2, this feature of the camera recommending

it for portraiture. The shutter, we would add, is the well-known Ernemann, and we need add no higher praise of its excellent workmanship.

In the matter of extension the camera is well provided; it racks out on its two struts to  $9\frac{1}{2}$  inches, and then pulls out (from plate to camera front) to a total extension of  $13\frac{1}{4}$  inches. As the lens is recessed about  $1\frac{1}{2}$  inches, a reduction of this latter length must be made, but even then the extension is more than enough for a  $5\frac{1}{4}$ -inch lens, and there are also means for affixing an auxiliary lens panel an inch forward.

At both short and long extension the rise of front (nearly one inch and by rack and pinion) is available. The extension at both full and half-way is one of the most rigid we have handled. There are certain other features we may refer to, such as the reversing back, lens shade, and side swing front (useful at times), but we have said enough to show that in the "Specto" the prospective purchaser of a reflex has almost as compact, as efficient, and, so far as we can judge, as strongly made an instrument as he can desire, for the comparatively small sum of £9 9s., with three double slides, but without lens. With the Staley Planastigmat,  $f/6$ , the price is £13 15s.

**Monochromatic Light-filters.** Made by Wratten and Wainwright, Croydon.

For the special work of the photomicroscopist, spectrophotographer, and others who require at their command a complete range of filters, Messrs. Wratten have prepared this set of filters passing very narrow bands of the spectrum. The filters are issued by Messrs. Wratten as of approximately equal luminosity and of (photographic) absorption such that they transmit about 1-30th of the incident light in the region of maximum absorption. The makers give the following specification of the filters:—

- a from 65 onwards towards the red.
- B from 66 to 61, and also a faint band in the red above 69, which it is not possible to eliminate.
- γ from 62 to 59.
- δ from 55.5 to 59.5, with a very faint red band at 70.
- ε from 55.5 to 52.
- η from 52 to 46.5.
- θ from 47 to 40.

The price of the set of seven filters, 2in. square, composed of film bound, not cemented, between glass, is 35s., including a case. The single screens are obtainable at 6s. each.

**"Ensign" Chemical Outfit for Autochrome Plates.** Sold by Houghtons Ltd., 88-89, High Holborn, London, W.C.

The solutions for the treatment of the Autochrome plates are very conveniently prepared in this set of Messrs. Houghtons Ltd., in which is included every reagent for the successive stages of that process. The solutions A and B for the first development—Messrs.

Houghtons retain the Lumière lettering of the baths—are supplied in concentrated form, one part of each having to be added to ten parts of water. The remaining preparations—with the exception, of

course, of the varnish—require to be dissolved only in the prescribed quantity of water, and are immediately ready for use. It may be noted, to Messrs. Houghtons' credit and discretion, that by an expedient which will be obvious to students of chemistry, they dispense with the sulphuric acid in solution C, obtaining the same result in the solution without compelling the user to handle the strongly corrosive oil of vitriol. The re-developer, as is proper—in the case of a preparation which requires to be used when freshly dissolved—is put up in small cartons. The whole set, we have found, answers excellently for the development of the Lumière plates, and costs, complete in its case, 5s. 6d. With the chemicals are included a set of gummed labels (for the solutions to be made up), and a card of abridged instructions, which can be kept before the worker. This latter, with the booklet, "Colour Photography with the Lumière Autochrome Plates," issued by Messrs. Houghtons Ltd. at the small sum of 2d., should prevent the Autochrome worker from making mistakes.

An Apparatus for Making Composite Negatives Direct in the Camera. Sold by Halford and Thomson, 4, Broadway, Hammersmith, London, W.

The reproductions on this page well illustrate two of the uses of a piece of apparatus which is now offered for sale after having been semi-privately used by a number of photographers in different parts of the country. Fig. 2 shows a specimen book of mounts, each of which, as can be seen from the photograph, is not more than

Fig. 1.

Fig. 2.

6 inches or 9 inches in height. The portrait shown in Fig. 1 is printed in one operation, from a negative obtained direct in the camera, and developed, also in one operation, in the usual way. It will be seen that the mount thus incorporated with the sitter on the negative is that seen in Fig. 1.

Again, the small model of a room seen in the hands of the boy in Fig. 3 has been utilised as the background in Fig. 4, the combining of sitter and background having been done entirely in the camera and without retouching and ordinary "faking" methods. The apparatus by which these effects were easily produced should certainly be of the greatest interest to photographers, and we will therefore give a short description of the appliance, as now placed upon the market, and of a demonstration of its action which was given us a few days ago in the studio of the inventor, Mr. W. Boyd Henderson, a photographer in Westbourne Grove.

The apparatus consists of a framework very similar to the skeleton of an Eastman roll-holder, which is mounted on a square open frame by struts which allow its distance from the supporting frame to be adjusted. The frame fits into the back of the camera, and the roller mechanism is thus supported inside the camera at a distance of, say, 3 inches to 4 inches from the focussing screen. It is, however, but the means of bringing into action the essential part of the apparatus—viz., a flexible band wholly of black paper with certain apertures in it, or partly of the paper and partly of celluloid, for the distinct purposes which will be seen in a

moment. In either case the band is wound across the space between the two rollers, and is caused to halt at any desired point by register marks on its edges and one centre mark on the framework which supports it.

Thus, if the apparatus is to be used for obtaining the photograph of a sitter three times on one plate, the black band with three apertures in it is moved successively into register with the centre, and three successive exposures made on the plate. The three portraits thus obtained on the one plate do not divide up the latter into separate sections, but merge into each other without

Fig. 3.

Fig. 5.

the sign of a join, so that all three may be printed as a complete photograph, or each one completed separately.

The procedure is slightly different but no less simple when producing an effect such as that in Fig. 1. The sitter is first photographed through an aperture in the blind of suitable oval shape. This is then wound on and replaced by a portion of the blind consisting of clear celluloid, with an opaque oval area corresponding with the aperture in the opaque part of the blind. The mount is photographed on the plate in any desired scale; the result is one negative, which affords Cosway and other effects at

Fig. 4.

one printing. The vignetting action of the blind allows of these operations being done with ease, and so long as the two exposures are properly timed there is no sign of the compound nature of the negative.

It is, however, in the use of the apparatus for employing miniature accessories as full sized backgrounds that the most ingenious application of the apparatus is found. Figs. 3 and 4 are examples. The manipulation is precisely the same as just outlined, that is to say, the sitter is photographed through a mask, any size and shape thought desirable, the complementary disc wound into place,

and a second exposure made on the miniature model of a room, a doorway, a wall, or any other object thought suitable as a background or accessory. The blinds, both "all-black" and "black and transparent," are obtainable in considerable variety, devised to serve the photographer in the production of commercial styles of portrait. Fig. 5 is an example of a Corot landscape used in this way.

We have not spoken of the amateur model of the apparatus devised to fit on the lens hood, but it has certain valuable properties for landscape photography in the way of equalising exposures and even of producing combination photographs in the field. The purely business and professional claims of the apparatus should be sufficient to engage our readers, for whose information we would say, in conclusion, that the apparatus is known as the "Thaumatoscope," and is sold at 30s., complete with six interchangeable blinds.

**PAGE-CROFT BROMIDE PAPERS.**—Bromide paper, in several varieties of tint—green-blue, grey salmon, buff, blue, and cream crayon—reach us from the Page-Croft Paper Company, Cooksey Road, Birmingham. The papers have the good qualities which we have discovered in other products coming from Mr. Page-Croft's, whilst the tints permit a wide range of effects, and are particularly amenable to schemes of contrast or harmony, by using the sulphide or other processes of toning the paper. The tinted bromides are put up in 6d. and 1s. packets.

**GLOSSY VELOX.**—Messrs. Griffin send us a sample of their Glossy Velox, representing an improvement in manufacture in respect of the surface markings to which glossy papers of this class are liable. The new grade of velox certainly enjoys a high degree of luminosity from them, and in both the "soft" (for strong negatives), and the "vigorous" (for thin negatives) yield results which call for little of the treatment with spirit-moistened cotton-wool by which such abrasion marks can usually be removed.

**CHRISTMAS MOUNTS.**—Under the title of "Unique," Mr. W. Tylar, of 4, High Street, Aston, Birmingham, has issued a set of folding mounts, suitable for use as Christmas cards, each set consisting of twelve mounts of assorted sizes and shapes, and twelve envelopes. The cards are white, with embossed borders, the "greeting" being printed in pale-coloured ink. The openings intended for the insertion of photographs vary in size and shape, and include both the paste-down and slip-in varieties. The price is 1s. 8d. per set, post free.

#### CATALOGUES AND TRADE NOTICES.

**HOBBIES FOR THE BOYS.**—Under this title Messrs. Butcher and Sons, Limited, have issued a list of specialties suitable for Christmas gifts for boys of all ages. They include magic lanterns, together with slides and outfits, cinematographs, working models of various kinds of engines, clockwork railway trains, trams, motors, model railway accessories, etc., at prices calculated to meet the requirements of all intending purchasers. A copy of the list will be sent on application, or the goods themselves may be viewed at Messrs. Butcher's, Camera House, Farringdon Avenue, E.C.

**VEROTYPE GASLIGHT PAPER.**—Those who would read the opinion of a connoisseur like Mr. H. Walter Barnett, and at the same time see for themselves the appearance of a print on this excellent gaslight paper, should apply for a new leaflet and specimen print to Mr. C. A. Rudowsky, 89, Chiswell Street, London, E.C.

WE REGRET to have to announce the death, on the 2nd inst., of Mr. Martin Jacolette, late President of the Professional Photographers' Association.

**THE UNITED STEREOSCOPIC SOCIETY.**—The result of the Flower and Fruit Competition of this society proved as follows:—First award: S. W. Shore, Barnsbury; second: W. Isherwood, Burnley; third: A. J. Snow, Walthamstow. The following received hon. mention:—Messrs. F. W. Pearson, P. Snow, and W. Isherwood. In judging the slides, Mr. E. Seymour said: "Flower and fruit studies, as a rule, are not a very strong class, but in this instance I think they are very good, both in number and quality. Nearly every slide shows excellent technique and very careful work. Many of them are so even that if technique alone was the standard it would be very difficult to judge them."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK

FRIDAY, DECEMBER 6.

Aberdeen Photo Art Club. Federation Portfolio.  
Aberdeen Photographic Association. Lantern Slide Competition and Selection of Set for Scottish Federation Competition.  
West London Photographic Association. "Old London." A. H. Blake, M.A.

MONDAY, DECEMBER 9.

Scarborough and District Photographic Society. "Architectural Photography." A. S. Tetley, M.A.  
Rotherham Photographic Society. "Flower Photography." E. Seymour.  
Bradford Photographic Society. "Mounts and Mounting." Percy Lund.  
Graysend and District Photographic Society. "Print Criticism." J. T. Dalladay.  
Cleveland Camera Club. "Architecture" by E. W. Jackson, per E. A. Wright.  
Derby Photographic Society. The Royal Photographic Society Affiliation Competition Slides for 1907.  
Manchester Photographic Society. "Photographic Chemicals."  
Aldershot Camera Club. "Rotary Carbograph Paper."

TUESDAY, DECEMBER 10.

Royal Photographic Society. "Agar-Agar in Emulsion Making and a Sepia Paper." W. F. Cooper, B.A., F.G.S., and W. H. Nuttall, F.I.C., F.C.S.  
Epsom and District Literary and Scientific Society. "Carbon Printing." Illingworth & Co.  
Leeds Photographic Society. "Still Life Photography." E. Seymour.  
Forest Gate M.M. Camera Club. "Photographic Chemicals."  
Chichester Camera Club. "Rotary Carbograph Paper."

WEDNESDAY, DECEMBER 11.

Borough Polytechnic Photographic Society. "Walks with a Camera in London." A. H. Blake M.A.

Richmond Camera Club. "Mountaineering in Switzerland." Julian Grande.  
North London Photographic Society. Lantern Slide Evening. Competition.  
Chelsea and District Photographic Society. "Control in Printing." F. Humpherson.  
Rugby Photographic Society. Exhibition of Novelties in Photographic Apparatus and Materials.  
Queen's Park Amateur Photographic Association. "Bromide Toning." John Baird.  
Wiglit Photographic Society. "Rotary Carbograph Paper."

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held December 3, the president (Mr. J. C. S. Mummery) in the chair. An audience as numerous as that which a month ago assembled to witness Mr. Grant's demonstration of the Autochrome process crowded the lecture-room of the Royal Photographic Society on Tuesday last, when Mr. John H. Powrie lectured on the Warner-Powrie process of colour photography. The lecturer commenced by briefly referring to the previous attempts which had been made to employ a linear filter screen as the basis of a one-plate process of colour photography. His own connection and that of Miss Warner with the process which bore their two names had arisen from the fact that shortly after taking up his residence in Chicago he had been called upon to give some advice to the International Colour Photo Company, which at that time was endeavouring to place the Joly-McDonough process upon a commercial basis. The method adopted in that company's laboratories was to rule the three lines of the filter by means of bevelled wheels which applied the ink, but the process was so expensive that the total output of a machine was only three screens, measuring 30in. by 24in. each, per day. He was thus led to devise a photographic method of preparing the screens, which consisted in printing from an opaque black and white linear grating, in which the opaque lines were double the width of the clear interspaces. By printing on this plate by bichromated gelatine in three successive operations,

and with each staining-up the impression in a red, green, or blue dye, it was found practicable to manufacture the screens at a cost and with a regularity which were sufficient for commercial purposes. With a small machine which he had in use in his laboratory a single workman could make per day thirty dozen 10in. by 8in. plates of 600 lines per inch—that is to say, of twice the fineness of ruling attempted in the McDonough-Joly process. Mr. Powrie proceeded to explain and illustrate on the screen the method adopted in printing the colour positive from the colour negative, and also of preparing the three continuous-tone positives from the single linear screen-plate negative. He exhibited a considerable number of lantern transparencies, which met with frequent applause from those present. He also dealt briefly with the possibilities of obtaining colour records on paper at a single printing, and explained the application of the triplicating method, details of which have already been published in our columns, to the production of prints on "Uto" bleach-out paper. In the course of a short discussion, Mr. Oliver Dawson asked why it should not be possible to employ the principle of the process, but with paper as a support for the screen ruling instead of glass. Mr. Powrie, in reply, pointed out that the screen-plate was necessarily obstructive of light to a considerable extent, and therefore was only applicable, so far as he could see, to the making of transparencies, the brilliancy of which could be enhanced by increasing the light behind them. In the case of paper one was limited by the powers of the paper to reflect light, and he could not see that there was any likelihood of success attending the efforts of experimenters in that direction. The Chicago firm which attempted to develop the McDonough-Joly process along these lines spent very considerable sums of money without success. On the proposition of the president, a very hearty vote of thanks was recorded to Mr. Powrie for his lecture.

**HULL PHOTOGRAPHIC SOCIETY.**—On November 28, Mr. Henry J. Comley lectured before the above society on "Three-colour Photography," dealing chiefly with the three-colour carbon process, but also drawing attention to the chief characteristics of one-exposure screen plates as illustrated by the Autochrome and Warner-Powrie processes.

## Commercial & Legal Intelligence.

**C. CORN, LTD.** (Photographers, Cardiff).—A 5 per cent. first mortgage debenture, dated November 8, 1907, to secure £1,600, charged on the company's property, including uncalled capital, has been registered. Holders: F. Greenslade, Cardiff; and F. J. Hughes, Woodhouse Road, Edgbaston.

**BRITISH PHOTO PAPER COMPANY, LTD.** (Lambeth).—Issue of £1,275 6 per cent. debentures, part of series created November 6, 1907, to secure £5,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. No previous issue of same series.

**EVIDENCE BY PHOTOGRAPH.**—In the Clerkenwell Police Court last week a plaintiff, asking for the committal of a debtor, said the man was well able to pay.

The Judge: But you must give me evidence of his means.

Plaintiff: I have a photograph here of his family. You can see by that that they are pretty well to do.

The Judge: It is rather unusual evidence, but I will look at it.

Plaintiff: This debt was for taking the photograph.

The Judge: To judge from appearances in this photograph he can pay.

An order was made, defendant not answering the summons. The committal was seven days in default.

**THE CARRIAGE OF PARCELS.**—In the Westminster County Court last week Mr. Dudley sought to recover damages from the London Parcels Delivery Company for non-delivery of goods within a stated time.

The solicitor for the plaintiff said he undertook to provide a company of actors for a cinematograph company, to play in dumb show a piece called "Mazeppa," with a view to it being reproduced as a cinematograph show. He ordered a number of properties and costumes from a firm in Middlesex Street, which were delivered to one of defendant's carmen on a Saturday afternoon. The carman promised to deliver them on Monday morning at Wembley, and the company travelled down there. The costumes did not arrive, and the actors had to return to town. Next day they went down again, but the costumes did not arrive until late in the afternoon, when the light was too bad for the photographs to be taken. Plaintiff claimed damages for the loss he had thereby been put to.

Mr. Frank Dudley confirmed his solicitor's opening. The part of "Mazeppa" was taken by a man who is paid £1 a day. The people who took the parts were stray actors out of employment, who were paid so much a day. Some were paid £3 or £4 a day when good acting was required. There was also a trained horse at £1 10s. per day.

Mr. Harrison, assistant at Messrs. Benjamin, theatrical costumiers, said that he told the carman the costumes were required for Monday morning, at 9.30, at Wembley, and the carman replied, "That will be all right." The carman did not know for what purpose they were required.

Defendants pleaded that it was unreasonable to expect them to deliver the goods at Wembley on Monday morning, when they were only handed in on Saturday afternoon. In any case plaintiff was only entitled to recover damages directly following for the breach of contract, which they could have contemplated.

His Honour allowed plaintiffs £15 for the wages paid on the first day, and £1 in respect of telegrams, etc. Judgment for £16, with costs.

**A BRISTOL BANKRUPT.**—The case of George Gibson, 23, Clarence Road, trading as "Late A. and G. Taylor," photographer, was heard in the Bristol Bankruptcy Court last week. The unsecured liabilities were returned at £268 12s. 6d., and no assets were shown. From the Official Receiver's observations it appeared that the debtor, who is forty-eight years of age, entered into partnership with a firm of photographers in Bristol in 1903, the debtor providing £100 capital, lent him by his brother. The partnership was dissolved in August, 1906, the debtor paying £50 for his half-share of the partnership assets and £50 towards the firm's liabilities of £178, for which the retiring partner held himself responsible. The debtor effected a private arrangement in November, 1906, paying a composition of 1s. 9d. in the pound upon liabilities amounting to about £300. The present liabilities include 238 claims, mostly by poor people, who have paid the debtor for photographs to be taken sums amounting in all to £110 3s. 8d. The debtor, about a year ago, executed two bills of sale covering his trade effects and household furniture, the whole of which, however, had been realised under a distress for rent, but did not produce sufficient to meet the landlord's claim.

**GAZETTE NOTICES.**—The following notices appear in the issues of the "London Gazette" for the past week:—Dividend: Arthur Holdsworth Leach, photographer, Haigh Street, formerly Brooklyn Terrace, and Commercial Street, all in Brighouse, Yorkshire, 9s. 6d. in the £1 (supplemental), payable on and after December 7 at Official Receiver's chambers, 29, Manor Road, Bradford. Intended dividends: John Edward Reeves (described in the Receiving Order as J. E. Reeves), photographer, 48 and 50, Hermit Road, Canning Town, E.; last day for receiving proofs December 18; trustee, Egerton S. Grey; Official Receiver, Bankruptcy Buildings, Carey Street, W.C.

**"HALF-TICK" PHOTOGRAPHY.**—During a case in the Clerkenwell County Court last week, which involved a question of account, his Honour (examining a ledger) asked: "What does the Half-Tick Photo Company mean?"

It was stated that a business was carried on under that name.

The Judge: I believe that in some business circles there is a term popularly known as "tick."

Counsel: This has a different meaning, your Honour.

The Judge: This is only half-tick.

Counsel: It means that you can have your photograph taken in half-a-tick, really less than a second.

The Judge: I see. This means no waiting—different from "tick."

## News and Notes.

**ERRATUM.**—A slip of the pen occurred in our brief notice given last week to the carbograph booklet of the Rotary Photographic Company. The word "ozobrome" should, of course, read "carbograph." We would not wish to raise confusion between the two processes, which are perfectly distinct.

**CRITERION.**—The many users of the products of the Birmingham Photographic Company, Ltd., which of late have come to the front, will be interested in an article published in the "Birmingham Daily Gazette" for November 27, which contains a biographical sketch of Mr. J. B. Brooks, J.P., the controlling interest in the Criterion firm. The article is one of a series on "Midland Captains of Industry," and relates the story of Mr. Brooks's successful business undertakings. Probably few users of Criterion gaslight papers or P.O.P. are aware that the destiny of their manufacture is in the hands of the successful commercial leader who has made the name "Brooks" synonymous in all parts of the world with comfort in cycle saddles. Mr. Brooks's firm is also a large maker of motor tyres. Some twenty years ago Mr. Brooks founded another distinct business for the manufacture of photographic printing-off papers and other accessories to the use of the camera. This trade steadily grew, as the increasing cult of the camera led to widening demands for all kinds of photographic materials, and Mr. Brooks ultimately converted this business into a private company, under the style of The Birmingham Photographic Company, Ltd. Land was acquired at Stechford, and there new premises were opened ten years since. These are also named The Criterion Works, where, in addition to special makes of printing papers, including the popular "Celario" gaslight paper, millions of postcards and useful incidentals, covered by patents, are turned out in the course of the year. The Stechford works are electrically lighted and equipped with an up-to-date plant. Active and capable as he has been in his long business life, Mr. J. Brooks has never digressed from his own immediate commercial interests. He has devoted himself absolutely to the building up of the prosperous undertaking of which he is the head, and has never therefore spared time for those extraneous duties which bring a man prominently into public notice.

**ANTI-HALATION.**—A French patent, No. 379,187, has been granted to the Société Lumière for the use of colloidal brown manganese oxide as the colouring matter for the film which is interposed between the sensitive emulsion and the glass as a means of preventing halation. It may be prepared either by warming together solutions of gelatine and potassium permanganate and mixing the brown liquid thus obtained with gelatine, or by adding ammonia to a solution of gelatine, a manganous salt and an oxidising agent, e.g., hydrogen peroxide.

**"VELOX" COMPETITIONS.**—The awards in the October competition are:—First prize, £2 2s.: A. E. Marley, Cricklewood, N.W.; second prize, £1 1s.: T. Griffin, Holborn, E.C.; consolation prizes of 5s. each: E. A. Mills, Rochdale; G. F. Manders, Limerick; F. N. Tipton, Bristol; B. C. Joy, Hampstead; H. W. Fortune, Harrogate; W. C. Collinson, Ipswich; Miss B. Cumming, Elgin Avenue, W.; T. Lord, Castleton, Lancs.; Rev. E. S. Edwards, Finsbury Park, N.; J. Worswick, Nelson; C. H. Krauss, Shepherd's Bush; R. T. Caudwell, Salisbury. The competition is limited to those who have never won a prize before.

**ARTIFICIAL LIGHTING.**—In reference to an article on artificial lighting, which appeared on page 907 of our issue for November 30, a correspondent writes asking us to give him the address of the London agents of the Litz gas-lighting apparatus referred to in the article. We should be glad if any of our readers could supply us with the desired information.

**COLOUR-PHOTOGRAPHY AT NEWCASTLE-ON-TYNE.**—Professor Mark R. Wright, M.A., will give a lecture on "Colour-Photography," with lantern illustrations, in the great hall of Armstrong College, Newcastle-on-Tyne, on December 14, at 7.30 p.m. Examples of colour-photography by prominent workers will be on view on December 14 from 2 to 5 p.m., and on December 16 from 11 a.m. to 4 p.m. Admission to the lecture will be free, though tickets

(6d.) for a limited number of reserved seats may be had on application at the College up to 5 p.m. on December 13.

**"THE PHOTOGRAPHER."**—It is announced that the New York professional photographic paper founded by Mr. J. C. Abel as the "Photographer" has been purchased by Mr. Frank V. Chambers, and has been discontinued with the issue bearing the date of October 15, 1907, and numbered 181. Mr. Chambers is proprietor of the "Camera," and three months ago established the professional "Bulletin of Photography," which journal will be sent to subscribers of the "Photographer."

**"THE PRACTICAL PHOTOGRAPHER"** announces that with the December number just issued it will cease publication. The "Practical" has undergone several changes of late, but its "studio" edition has, under the editorship of the Rev. F. C. Lambert, been, perhaps, of too high a standard to reach a wide circle.

**CARL HENTSCHEL (1906), LTD.**—On and after December 1, the two branches of Carl Hentschel, Ltd., at West Norwood, viz., the Colourtype Works at Knight's Hill and the Meisenbach Works at Wolfington Road, will be amalgamated and worked in common from one office at Wolfington Road, to which all communications should be sent. Mr. Fogwell surrenders his old duties in order that he may from the Fleet Street office personally assist Mr. Hentschel and the board in the general control of the business. Any friends who have been accustomed to seeing Mr. Fogwell personally will now kindly note that he will be pleased to see them in Fleet Street instead of at West Norwood.

**A NEW "LORNA DOONE."**—The new edition of "Lorna Doone," which is to be published in a very few weeks by Sampson Low, Marston, and Co., Ltd., who were R. D. Blackmore's own publishers, will throw new light on the real people and the real places of the West Country classic. It is to have fifty pages of illustrations, including all the places prominently mentioned in the novel, and while these will dispel the cherished idea of the inaccessible Doone Glen, guarded by the great Doone Gate and the fearsome water-slide, they will give a good idea of the glorious land of moors and rills that inspired Blackmore's book.

The editors and illustrators of the book (Mr. H. Snowden Ward and Mrs. Catherine Weed Ward) have confirmed and corrected many old identifications, and added a number of new ones. The church at Oare, and the scenes chiefly visited by tourists are all represented, but there are also such subjects as the real "Plovers Barrows," the "long gun at Yenworthy," with which a Doone was shot, Weir Water, and the Robbers' Bridge, said to be where the real Doone settled before going to Badgery, Glenhorne Landing, where Jeremy Stickles' men waited until the time to attack the Doones, the district of the Wizard's Slough, connected with the terrible death of Carver Doone, Lanacre Bridge, where Stickles narrowly escaped, and even the hostelry at South Bolton where he filled the flask that saved his life.

The Spit and Gridiron at Porlock, where Jan Ridd bought his powder and lead from Mr. Pook; the Gartered Kitten, at Dulverton, where Uncle Huckaback threw; the church at Watchet where Lorna's mother was buried, and the Warren Farm, where Simon Carfax and his miners slew several of the Doones, are all illustrated.

**RAJAR (1907), LTD.**—Messrs. Rajar, Ltd., write:—We beg to inform you that a new company under the name of Rajar (1907), Ltd., will be incorporated in a few days with the object of taking over Rajar, Ltd., as a going concern. The new company are taking over the assets and undertaking to discharge in full all the liabilities of the old company. The management remains the same.

**A RECORD IN ENLARGEMENTS.**—Mr. S. H. Fry, the well-known enlarger of Frisian House, Highbury Grove, London, N.W., has shown us within the past few days an enlargement which, it would seem, he is just in assuming to be a record in size and degree of enlargement—among orders executed in the ordinary way of business. Larger prints have been made for show or advertisement purpose, but the making for a customer of some half-dozen enlargements measuring no less than 50 x 112 inches, and this from a negative, only 2½ x 1½ inches, would seem to be a record in the enlarging trade. These dimensions, it will be seen, represent a degree of enlargement of fifty times, and it says a good deal for

the skill of Mr. Fry's staff and their ability to deal with any work, great and small, that the technique and quality of the large prints are excellent, and the definition, when viewed at a normal distance, equal to what one gets in a 20 x 16 enlargement. It may be of interest if we add to this notice of our Frisian friends' achievement that the tiny negative was on a Lumière square plate, and was exposed in a "Blocknote" camera. The result is a tribute to the chemical and mechanical properties respectively of these articles.

THE "RAJAR" CAMERA offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P. has been awarded to Mr. H. Bunce, Caterham, his print having been judged the best received during November. The paper on which the print was made was purchased from Messrs. Kodak, Ltd., 17-61, Clerkenwell Road, London, E.C.

SIR W. ABNEY ON COLOUR PROCESS.—On Wednesday, November 7, a general meeting of the Central Technical College Photographic Society was held, with the president (Professor H. E. Armstrong) in the chair. Sir W. de W. Abney gave a most interesting demonstration of colour photography.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

THE ULTRA-VIOLET RADIATION OF ELECTRIC LAMPS.

To the Editors.

Gentlemen,—The passage from von Hübl's paper, referred to by Carnegie, not only refers to the absorption of the ultra-violet rays by the glass of the tube, but also to the fact that von Hübl's "practical work" includes the use of the lamps for the illumination of subjects to be copied and for printing, both on to silver paper and bichromated collodis. This naturally assumes a negative, which would be on greenish glass, the latter being a very strong absorbent of ultra-violet rays.

With regard to the absorption of the ultra-violet by the glass of the mercury-vapour lamp, I have had an opportunity of photographing the spectrum of two lamps, one with ordinary glass and the other constructed of the Jena Uvial glass. No variation could be detected in the two spectra as regards the ultra-violet, in both cases  $\lambda$  3390 being the last line recorded. This abrupt absorption is due to the loss of the lenses used in the spectrograph, which were single landscape lenses of a total thickness of about half an inch. A metal diffraction grating being used, and not a replica, there was no absorption caused here.

With regard to your correspondent's assumption that there would be a richer emergent ultra-violet radiation from the mercury-vapour lamp than from the enclosed arc, this would depend entirely upon whether the mercury-vapour was richer in ultra-violet than the enclosed arc. It is, I think, an open question, and I do not believe it is to be the case.

The mercury lamp is practically an arc in a vacuum, and this does not give a rich ultra-violet spectrum between  $\lambda$  4000 and 3390, which may take as the limit set by the absorption of glass. The lines in this region are 3984 (4), 3663 (5), 3654 (5), 3650 (10), 3390 (3). The figures in brackets represent the relative intensities of the lines. One or two iron lines are also generally to be photographed.

In the enclosed arc one has to deal with not only the carbon and hydrogen spectra, but also the inevitable impurities, such as calcium, which in the said region is extremely rich in intense lines and bands, not also aluminium and iron. Although I have not made direct comparison of this region from the two sources an examination of numerous negatives, all taken on the same make of plate at different times, conclusively proves that the enclosed arc gives, photographically, a much greater effect than the mercury vapour tube.

With regard to the non-appearance of the quinine fluorescence in the mercury light, might I suggest that a possible explanation lies in the fact that this fluorescence is excited by a particular ultra-violet region, which may be missing in the mercury tube. My idea is that in the enclosed arc one has broad bands, whilst in the mercury tube one gets isolated lines; therefore the latter may just miss that particular region which excites the fluorescence of quinine. This is but a suggestion, and not stated as a fact.—Yours faithfully,

Ealing.

E. J. WALL.

To the Editors.

Gentlemen,—Referring to Mr. Douglas Carnegie's letter in your last issue, and his experiments in connection with Baron von Hübl's statement that the glass cylinder surrounding the lamp absorbs the greater part of the ultra-violet rays, we think that Baron von Hübl's experiments were made with old patterns of enclosed arc lamps. In the "Jandus" photo-arc lamp the enclosure consists of a cylinder of special glass which is extremely transparent to violet and ultra-violet rays.

Mr. Carnegie's interesting experiments with quinine citrate can be supplemented by the following experiments:—

If a sheet of ordinary glass is held near the light from the Jandus photo lamp, the glass will become to a certain extent fluorescent. Uranium tinted yellow glass shows this fluorescence to a very marked degree. The only satisfactory way to examine the composition of light is with a spectroscope. Even a visual spectroscopic examination gives a very good idea of the composition of the light. Lights apparently the same in colour often contain widely varying amounts of actinic or non-actinic rays. Even daylight from a good north aspect will show marked differences in the brightness in the actinic (violet) end of the spectrum.—Yours faithfully,

THE JANDUS ARC LAMP AND ELECTRIC CO., LTD.

A. DENMAN JONES, Works Manager.

Hartham Works, Hartham Road, Holloway, London, N.

December 3, 1907.

## PORTRAITURE BY ARTIFICIAL LIGHT.

To the Editors.

Gentlemen,—In the article in your issue of November 22, entitled "Portraiture with the Mercury-Vapour Lamp," by Mr. Geo. R. Henderson, I think it is a pity that he is not satisfied with extolling the merits of his own, but must begin by trying to depreciate other systems. Nearly every statement in the second paragraph can be flatly contradicted, and, indeed, shows very little knowledge of the subject. A reference to your issue of November 8, I think, is the best answer that can be given to this paragraph, especially referring to the article entitled "The Enclosed Arc for Studio Portraiture."

It can hardly be claimed as an advantage that, "although for ordinary purposes the plates have been of the same speed, when used with the mercury-vapour lamp, each plate has required a different exposure." Further than this, as you have to "expose for six seconds," and "in no case exceeding nine or ten seconds," I should think that Mr. Henderson had himself quite disposed of any claims the mercury-vapour lamp may have for portraiture work. The exposure with enclosed type lamps, as your Mr. Hewitt's article referred to above, page 841, last paragraph, is a quarter of a second.

—I am, yours faithfully,

J. O. GIRDLESTONE.

Westminster Engineering Company, Ltd., Willesden, N.W.

November 27, 1907.

## THE LATE MR. A. L. HENDERSON'S PHOTOGRAPHIC LIBRARY.

To the Editors.

Gentlemen,—It may interest the readers of your paper to know that I have presented to the Guildhall Library, of the Corporation of the City of London, the photographic library of the late Mr. A. L. Henderson, thus placing within reach of all interested in photography the vast amount of information contained therein. Amongst the collection are bound volumes of your journal, from 1859 to 1906, 58 volumes "British Journal Almanac," and the "Photographic News Year Book, 1862-67, 1869-71, 1873-94, 1902 and 1904, 35 volumes; also the "Photographic News," Vol. 1 to 40, 1859 to 1896, 40 volumes.

W. LEWIS GRAY, son-in-law of late A. L. Henderson.

Westmoor Hall, Brimsdown, Middlesex.

November 26, 1907.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- T. Bell & Co., 35, High Street, Chatham. Two Photographs of the Bend of the Argyll and Sutherland Highlanders.
- J. Totty, 1, Chapel Street, Southport. Photograph of the Southport and Birkdale Postal Military Band.
- W. C. Harrison, 69, Southtown Road, Great Yarmouth. Photograph from Print of N. E. View of Burgh Castle, near Great Yarmouth.
- E. Roberts, Cartref, Toller Road, Leicester. Photograph of Evan Roberts.
- Capt. H. Owen, J.P., The Quarry, Stourbridge, Worcestershire. Photograph of the China Clipper ship "Sir Lancelot" Under all Sail. From a Black and White Drawing. Photograph of Ship "Red Jacket" amongst the Ice off Cape Horn in August 1854. From a Black and White Drawing.
- R. Thirlwell, 21, Bridge Road, Stockton-on-Tees. Photograph of Stern View of Model of Steam Ship "Mauritania."
- A. A. Bess, Amesley House, Westwell Road, Stratham Common, London, S.W. Photograph, Seashore with Donkeys, Goats, and Boys, Greece at Littlehampton, July 6, 1907.
- S. H. C.—1. Plane parallel glass optically worked so as not to impair the definition of the lens in any way. 2. Any series of filters can be obtained in this form, but the fact is certain to be stated in any list or catalogue. 3. Certainly. 4. For outdoor work the X2 times will be sufficient, but for stained glass we should advise you to use the X7 times. You appear to have the corrective action of the two screens interchanged in your mind. 5. The other (X2) screen will be sufficient. 6. Certainly, wherever there is a wide range of luminosities in the scene, and where portions admit of shading. 7. Only in event of using lenses of very large aperture— $f/3.5$  or  $f/4.5$ .

VARIOUS.—1. If a whole-plate lens is used in a half-plate camera, is every  $f$  value doubled? 2. A writes a book, which he illustrates with photographs, and makes an arrangement with B, a photographer, to supply him with them from his stock of negatives. Among them are several portraits which were taken privately and paid for by the sitters, CCC, persons since dead, but whose relatives, DDD, are still living. Has B any right to use the portraits CCC without the consent of DDD?—X. Y. Z.

1. No, it remains the same. 2. There is no restriction to B's use of the portraits unless the copyrights in the photographs have been registered, and also transferred to survivors of CCC.

BRITISH JOURNAL (Cape Town).—Either a folding camera, such as (2) or one of the reflex type. The latter are largely in the majority among process photographers working under conditions which do not compel them to carry the camera long distances. No. 3 is a first-rate instrument, but there are altogether thirty makes of reflex cameras. See the "Almanac" just published. We should advise you to select one of this type which possesses ample rise of front, double extension, and ready alteration of shutter-speed. The higher-priced cameras are worth what they cost.

C. W. THOMPSON (Colombo, Ceylon).—We presume you refer to the Lumière, Warner-Powrie, and other processes. We can best refer you to the article on them in the "Almanac" just issued.

COPYRIGHT.—I am an author, and occasionally give sittings to professional photographers, at their request. I pay them nothing, and they give me a few copies. It is understood that they may sell as many as they please. I think of prefixing a copy of one of these to a forthcoming work. Am I at liberty to do so?—F. S.

The copyright is the photographer's, and legally must not be used without his sanction. Most usually a photographer will

allow a sitter such as yourself to use the photograph for his personal purposes.

REDUCER FOR BROMIDES.—Can you give me any advice as to what generally used by artists and others for dissolving away reducing a part of the image on a bromide enlargement without leaving any stain? A one-solution reducer preferred.—ARTIST.

Ten per cent. solution of iodine in potass. iodide solution, 30 minims; 10 per cent. potass. cyanide solution, 10 minims; water, 2 oz.

PHOTOGRAPHS ON IVORY.—I should be glad to know if I can obtain any information in back numbers of "B.J." describing process of painting images on ivory for miniature painting. Also please state name of firms who do this work. Are there any books on the subject?—H. C. JOHNSTONE.

Photographs on ivory, for miniature painting, are made by the carbon process. The pictures are first developed on temporary supports, and then transferred to the ivory. The method of doing that was described in an answer to a correspondent in the issue for November 22, page 895. Working details of the carbon process are given in the "Autotype Manual" and Illingworth's book on the carbon process. Both the Autotype Company and Messrs. Illingworth and Co. will make prints on ivory for you.

EMBOSSING PRINTS.—I have been requested by a customer to copy the enclosed photograph and mount them in the same way.

I do not know how it is done, I would be glad if you would be so good as to let me know in the next issue of the "Journal." I would like to know if it needs any special appliances. If possible please state where to be obtained. It is only the raised mounting I wish to know how to do. I am fully acquainted with the glazing.—A. BERRY.

To produce the relief an embossing press is required. Presses for the purpose are sold by such houses as Fallowfield, Houghtons, and the like. These are screw presses furnished with metal discs with openings of the size and shape of the raised portion desired. The enamelled print, after being trimmed, is put into the press and pressed up. It is then fastened on to a mount with thin glue, or starch applied round the edges. The print has been returned to you as requested.

BLEACH-OUT PAPERS.—Can you tell me where I can obtain a bleach-out colour printing paper called, I believe, the "Uto"?—STEVENS.

Oliver Dawson, 254A, High Holborn, W.C.

A. W. H. P.—You are mistaken. The British patents for the Krayn process are dated September 22, 1905, and January 1, 1906. The German patent is dated September 24, 1904. You shall be most interested in seeing the specimen plates.

J. S—AND SONS.—We are much obliged to you for the T. query circular, but it appears to contain no new developments in the free-portrait fraud.

R. N. HARMER.—We do not understand your query. A white effect is usually obtained by blocking out on the negative. Why not send us a specimen postcard?

"UNOFOCAL."—There is not a great difference between the lens. We should select the "A" or the "B 1."

MOTOR.—They are not entitled to represent themselves as holders of a Royal appointment.

\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

At the R.P.S. on Tuesday a paper on the use of agar-agar in emulsions, particularly for direct sepia bromide paper, was read by Messrs. W. F. Cooper and W. H. Nuttall, by whom a most comprehensive series of experiments have been made. (P. 946.)

Portraiture by artificial light and stand development occupy our correspondence this week. (Pp. 949-50.)

Professor Namias and a colleague have failed to find any advantage in a recent modification of the persulphate reducer in comparison with the usual formula. (P. 940.)

A writer in the "Amateur Photographer" has devised a novel use of the bromoil process, namely, for automatically brightening the shadows of bromide prints. (P. 943.)

A brief biography and an appreciation of the late Martin Jacolette appear on p. 941.

Dr. Sheppard reports progress in the Krayn screen-plate process. (P. 944.)

Mr. W. J. Casey, of Raines and Co., mentions a precaution in making negatives for the post. (P. 943.)

In "Wayside Notes" the "Man on the Road" comments on some matters of advertising for photographers and on a point of importance in Christmas business. (P. 935.)

Mr. Rawlins last week at the Blenheim Club demonstrated his method of working the oil process. (P. 941.)

Multiple portraits, a stereoscopic tripod head, and a daylight development apparatus are among the patents of the week. (P. 943.)

The alteration in rapidity consequent upon using a long-focus lens in a small camera may sometimes have a practical effect. A note on this point appears on p. 934.

## EX CATHEDRA.

### The Art of being Inaccurate.

The present boom in colour photography has compelled those who devote their time to the instruction of people less wise than themselves to attempt the explanation of the principles of three-colour photography. This is, perhaps, not a particularly easy matter, and it involves one very troublesome point, that is, the explanation of why we print in blue, red, and yellow when the primary colours are blue, red, and green. In the beginning, this is not an easy thing to understand, and when one does understand it fully it is not simple to explain. But it can be explained by those who take the trouble to express themselves clearly, and there is no excuse for deliberately adopting a wrong explanation just because it is easier to convey. There have been many instances of would-be authorities attempting to explain the whole thing on the basis of red, blue, and yellow primaries, but perhaps the worst instances are those in which it is suggested that after all it is little more than a matter of terms, and that we may just as well speak of red, blue, and yellow as of red, blue, and green, the inference being that there is only some slight difference of opinion as to the third primary. Such an explanation will never help any one to understand that the pigmentary primaries are really the complementaries of the true primary colours, and if this essential point is shirked it is quite impossible to explain three-colour photography.

\* \* \*

### A New Spectrograph.

Dr. R. H. Blochmann describes in the "Zeitschrift für Reproduktionstechnik" a new and simple form of spectrograph, which he specially commends for testing two plates at once. The apparatus consists of a brass tube, at one end of which is a sheet of ground glass, which practically becomes the source of light; behind this is the usual slit, collimator lens, and a Fresnel prism, so that the rays of light are split up into two equal beams, which, falling on a grating replica, give two spectra, one above the other, on strips of the two plates to be compared. The camera is designed for strips 2½cm. by 9cm. The apparatus is made by Schmidt and Haensch, of Berlin.

\* \* \*

### Film Thickness And Colour Sensitiveness.

Dr. E. Stenger, of Berlin, has been investigating the influence of the thickness of the sensitive film on colour-sensitiveness, and comes to the conclusion that with increasing thickness of sensitive film there is increasing colour-sensitiveness. There is a limit to the permissible thickness, not only on account of slow fixing and washing, etc., but also on account of the slow drying of the plates—that is, as they come from the coating machine. Plates which are very slowly dried lose in sensitiveness, and any inherent fog increases. The author

also incidentally remarks that the generally accepted opinion that thickly-coated plates enable under-exposure to be better compensated for than do thinly-coated plates is erroneous.

\* \* \*

#### Long-Focus Lenses in Small Cameras.

Our "Answers to Correspondents" columns last week contained a curious question, to the effect whether the use of a whole-plate lens in a half-plate camera doubled the  $f$  values. We may have been wrong in our interpretation of the question, but, as we read it, it appeared to suggest that the querist was doubtful whether the whole-plate lens would not be slower in the half-plate camera than in one of whole-plate size. This, of course, could not be the case, but probably many photographers have failed to notice that the contrary is sometimes true. That is to say, that a long-focus lens may require somewhat less exposure when used in a small camera, even though the  $f$  values of the stops remain the same. This is due to a circumstance that we mentioned in a recent note on even illumination in printing. If using a large-aperture lens of, say,  $f/5.6$ , there is considerably less illumination near the margins of the field than in the centre of the plate. The falling-off may be 50 per cent. or more, in which case an exposure just sufficient in the centre of the plate is far too little at the margins, and the general effect is one of under-exposure. This is one of the numerous cases in photography in which we have to make a compromise. We must increase the exposure in the centre to avoid under-exposure at the margins, but the necessity for this increase becomes less and less as we diminish the size of the plate. It may, therefore, happen that a small plate only occupying the centre of the field may require very much less exposure than a large plate that fills a big view angle. Of course, a great deal depends on the character and type of the lens. With some large-aperture lenses oblique pencils are not materially cut down until the view fills a fairly wide angle, but with others the full aperture is only effective over a very small patch in the centre of the plate. The matter is, however, worth remembering, as it is sometimes desirable to take it into account.

\* \* \*

#### Defective Apparatus.

In an article that recently appeared on scamped work in the manufacture of photographic apparatus we see that one of the complaints made concerns the use of thin porous wood in the shutters of the dark slides. An instance is given of every shutter in a set of three slides containing one patch of porous wood that let the light through sufficiently to fog the plate. Blame is, of course, laid on the maker for the use of too much machine-made work and for the omission to test the apparatus properly, while some is also awarded to the customers who demand cheap work. There is, however, a great difference between cheap work and bad work. If the customers only demanded cheap apparatus, it could be supplied to them in a perfectly efficient condition. The trouble is that they want the real price to be very low and the apparent price very high. That is, they want apparatus that looks expensive and is really very cheap, which means that a good part of the cost has to be expended in meretricious finish and in poor qualities of expensive material. They also demand elaborate movements and lightness, which means the skimping of material where solidity is desirable. A mahogany dark slide of double book form is not a thing that can be made well and be at the same time very thin and cheap. If thin the shutters must be made of wood of the very best quality, and the price will not admit of this. Cheap mahogany is a very treacherous material, and if used trouble of one

sort or another is sure to be met with. Then, again, triple-extension baseboard to be steady and reliable requires good workmanship, fitting, and material, and should be more or less weighty. In such a piece of mechanism rigidity cannot be expected under any other conditions, but the people who demand such baseboard are not prepared to pay the necessary price. The kind of apparatus that they want, if properly and scientifically constructed, would cost double what they are willing to pay, hence the grumbles of the ill-treated economical amateurs. They could have all they really need at a low price if they would only be content with simpler and heavier construction and less show. At the same time, we must admit there is a good deal of truth in the grumbles concerning inefficient testing. Judging by the apparatus of good quality that has passed through our hands, it is evident that a certain proportion of manufacturers have no carefully elaborated testing system, such as is essential to prevent the issue of defective articles.

\* \* \*

#### Lady Novelist's Photography.

Morals and all the proprieties we expect and obtain in the publications of the "Religious Tract Society," so, perhaps we must grant the writers, whose work it issues to the world of the circumspect and straight-laced, some little license in some respect. Surely even the young person for whom a recent volume by Mrs. Vaizey is intended will find it difficult to repress a smile when they read how the mystery of the story is cleared up—namely, the registration upon the photographic plate of the features of a thief. Not everyone who photographs by permission in a man's house and is afterwards open to suspicion in connection with the simultaneous disappearance of valuables from a desk is so fortunate as to find a portrait of the thief a work on developing his plate.

#### DEPTH WITH DIFFERENT LENSES.

A RECENT query in our "Answers to Correspondents" column raised once more the everlasting subject of the variation in depth that exists with lenses of different types. On this matter much misconception seems to exist. On the one side we have people declaring that depth depends solely on aperture and focal length, and is independent of all constructional features—which statement is scientifically quite wrong—and on the other side we find persons who seem to expect that every lens made gives a measurably different degree of depth.

It should be understood that constructional peculiarities of the lens only affect depth when the object in sharp focus is near, and that the only constructional peculiarity of importance is the position of the stop, the effect of which is very small. In the case of distant objects it is correct to say that depth varies solely with focal length and aperture, provided we consider the angular and not the effective aperture, and provided the lens is quite free from spherical aberration. In these circumstances the lens should give results as regards depth in exact agreement with the calculated results given in the tables, though the presence of even a small amount of aberration will upset this agreement. In point of fact the calculated results can only apply with exactitude to an ideally perfect lens, that is, to one that converges all the light received from a distant point to a perfect point focus, or produces a perfect cone of light bounded by straight lines. Such a lens does not exist. The image of a point is always a disc, and, however small the disc may be, a close analysis of the structure of the light pencil will reveal the fact that caustics exist in it, and that it is therefore not a perfect cone. A simple test is to throw the image of the point a little

of focus and examine the small disc of light then apparent. On one side or the other of the true focus the disc will generally show a dark centre bounded by a ring of light, which appearance indicates unmistakably the existence of caustics and of slight spherical aberration. In these circumstances depth must be affected, even if only to a very small degree.

The manner in which depth is affected by aberration can be easily proved by any one possessing a camera and lens of indifferent quality, say, a cheap "single landscape" lens. Prepare a small source of light by placing a pinhole made in a thin sheet of metal in front of an incandescent gas burner. As the experiment is only for illustration purposes, the light may be near the camera. Focus sharply on the pinhole, and then rack the camera until the image is an appreciable disc. This disc must not be too large or the test will break down, therefore keep the disc as small as is convenient for after measurement. Next, keeping all the adjustments of camera and light exactly the same, make a series of exposures recording the exact size of the disc with every stop of the lens, from the largest aperture possible down to the smallest. Then measure the diameters of the discs obtained.

This series of disc images now represents the disc of confusion produced by each stop, and, according to theoretical laws governing depth in ideal conditions, the size of confusion should vary in diameter in exact proportion to the size of the stop. Check the measurements against each other, and it will almost certainly be found that the discs do not by any means vary in the same ratio as the stops. In one lens with which we tried this ex-

periment, we found not only that the ratios were all wrong, but that the two largest stops, and also the "naked" lens without any stop, gave discs of exactly the same diameter. All these stops were bigger than the one the lens was intended to be used with, but even with the stops that did not exceed the maker's maximum the ratios were completely wrong. As a matter of fact, the whole of the discs were much too small, and as a result the depth given by the lens was always considerably greater than the calculated amount. This was not a good lens at any aperture, but the conditions that prevailed as regards the disc of confusion were only exaggerated examples of what occurs to a certain extent with every lens. With a very finely corrected lens the variations may be unmeasurable, and such a lens will probably work almost exactly in accord with theory. A poor lens will depart from the theory, and will give greater depth with much inferior definition.

When depth varies on account of aberration, it sometimes varies differently on opposite sides of the point in sharp focus. The near depth may be increased, and the far depth diminished, or vice versa. Possible misconceptions may arise from two lenses of different character being compared, for as a rule it is near depth that is most usually considered. The difference between well and poorly corrected lenses is also often exaggerated, owing to the fine definition attainable with the former type. This sets such a high standard that an amount of confusion quite tolerable with the poor lens is intolerable with the other. Therefore, as regards depth the fine anastigmat is likely to be unfairly judged if visual tests alone are relied on.

## WAYSIDE NOTES ON CURRENT TOPICS.

grand rebuked. In my last instalment of wayside experiences I used the expression "butcher, baker, candlestick-maker" in rather a pharisaical spirit, and lo! I am brought to book. By candlestick-maker. He is a real craftsman, and his candlesticks are things of beauty. If you know that delightful monthly "Studio," you will occasionally have seen reproductions of the kind of work my friend produces—and of which he is, not unreasonably, proud. I tried to conciliate him by saying that his candlesticks were not the ordinary candlestick of commerce, but would not be silenced. He asked me whether I had ever seen a candlestick in china or tin that pretended to be other than what really was. Had I ever seen one that was not strong—had I ever seen one that showed that the man who made it could have done his work more faithfully had he not been cut down in price by his neighbour? Of course, I had never examined the candlesticks I have had given to me at the country hotels very closely, and so, for lack of any effective reply, I had to agree with him. And then he asked me whether I could apply the same argument to photographs!

A few days later we were at the "Royal" together. He addressed the William Crooke wall, but asked where were the other professionals in the section seemingly devoted to their work. I assembled by saying they preferred to take the risk of acceptance by competing in the Pictorial Section. And then he followed the matter up. "Yes," he said, "Furley Lewis, Oscar Hardee, E. Symes, Whitehead, Treble; that's five." I pleaded that though I know the profession well, I could not be expected to know every man whose work was in the room. "Of course not. I give you the benefit of the doubt and say there are twenty. Now can you tell me any other branch of the arts in which at any exhibition the amateur element should be so overwhelm-

ingly more in evidence than that of the men who made their living by it?"

In vain I argued that it was the fault of the great British public and that the professional has to bring up his family. He pointed to the Oscar Hardee "Bruges" and said, "Why don't they take a camera on their holidays?" "Well, with a good many of them it doesn't run to any holiday at all—let alone one on the Continent." Instantly he turned to the same man's "A London Portal." "Do you know where that is? That's the Tower Bridge—and the chances are that it was taken on a Sunday, because the bridge is never so free from traffic as that when I see it on week-days." I did begin to regret my unlucky reference to his occupation.

"It's like this. Five out of six of your friends call themselves photographic artists, and they know about as much of art as they do of the differential calculus. And they think they can fool the public by sticking up the signs, Gainsborough Studio, Romney Studio, Vandyke Studio, Rembrandt Studio, while all the time the public that they pretend cannot appreciate good work is buying little handbooks and portfolios of reproductions of the work of these old masters, literally by hundreds of thousands. You must remember that the British public of to-day is not the same as that of fifty years ago, or even twenty years for that matter. We candlestick-makers you despise so much have learned that lesson; we know that the ability to hammer metal is not more valuable than having had an art training that has taught us the principles of designing. Can you say as much for your friends the photographers?" I am wondering now whether the makers of the weird shapes in rolls that I sometimes get handed to me have had Polytechnic courses in designing. And

at Christmas time the butchers display beribboned and rosetted carcasses of prize beasts.

I do not want another ragging, so I think I had better withdraw my reference to "the butcher, the baker" as well as to "the candlestick-maker."

\* \* \* \*

A photographer in one of London's western suburbs has hit upon an idea for turning the prevailing Limerick craze to his own advantage. Inserting the first four lines of the Limerick in a local paper, he stipulated that the fifth line should be filled in upon postcards that he would supply gratis. He offered three cash prizes amounting in all to two guineas, and twenty-five prizes in the form of a cabinet photograph. Over two thousand replies were sent in, and as his is a studio in which work at "popular prices" is done, the scheme no doubt repaid him well. For those who wish to imitate him it may be said that the first four lines ran as follows:—

There's a place in ——— High Street  
Where they take your photo a treat  
———— the name

For they're good at the game,  
And the first three prize-winners' lines to complete were:—  
And they give satisfaction complete.  
And their rivals all take a back seat.  
And ——— a firm you won't beat.

\* \* \* \*

In case my friend the candlestick-maker should read the foregoing, I would explain that the photographer responsible for the competition displays on his signboard the terms "Photographic Contractor."

\* \* \* \*

How many of my readers, I wonder, find any amusement in rummaging through secondhand booksellers' shops? From his occasional references to the subject, one may easily gather that the Editor of the "B.J." yields to the temptation at times. Yes, temptation is the right word; I know that now that the old Wych Street has been pulled down in the Strand widening scheme, I can get from the Law Courts to Wellington Street much more quickly than I could when Wych Street was a "short cut" that always involved at least twenty minutes going through the "twopenny" boxes of the secondhand booksellers most of whom have now migrated to the street, well known by name at least to most photographers, called Charing Cross Road.

My last purchase was made just after the report of the P.P.A. meeting devoted to "Advertising" appeared in the "B.J." I confess that I was under the impression that advertising was comparatively modern, yet in my "twopenny" book I was taught differently. "Saunterings In and About London" was published in 1853, and describes the wanderings of an Austrian exile in London. One of his first impressions of London is that of various advertising methods. "There is no other town in the world," he writes, "where people advertise with so much persevering energy—on so grand a scale—at such enormous expense—with such impertinent puffery—and with such distinguished success." And again, "It is either advertising or being ruined. We have said it before. Many of our readers will think this bold and unwarranted assertion. It is neither the one nor the other." And then he goes on to describe the business of "Mr. Bennett, who keeps a large shop of clocks and watches in Cheap side." This generation knows the shop as that of Sir John Bennett; and probably very few know that he spent £900 on the insertion of his advertisement on the back cover of the Great Exhibition catalogue. Presumably the exhibition referred to is that of 1851 in Hyde Park. I should have liked to have been present at that P.P.A. meeting, and to have had my "twopenny" find wherefrom to have read extracts.

\* \* \* \*

In the advertising pages of a recent issue of the "B.J." there was a list of the latest dates upon which to post photographs in order to reach their destinations by Christmas. It seems to me that an important addition would have been a reminder of the fact that in the week or so immediately preceding the holidays there have been for some years now bad delays in the Postal Service. Towns in the provinces that are supposed to be within four or five hours' postal transit of London were kept waiting nearly as many days last Christmas. I know for a fact that in Manchester and Liverpool parcels arriving by passenger train service came through much more quickly than by parcels post. This should be remembered when ordering material; platform stocks are not likely to run out unexpectedly, but gaslight and bromide papers are, and therefore it is as well to be on the safe side by ordering a sufficient quantity to cover a big rush of orders. A similar warning applies to trade enlarging and printing orders—most of the leading houses in which business are situated on the outskirts of London, and which are therefore likely to be affected by the Christmas pressure on the postal service.

THE MAN ON THE ROAD.

## EXPERIMENTS ON THE GRAIN OF SILVER IMAGES OBTAINED IN THE WET COLLODION PROCESS.

(A paper read before the French Photographic Society.)

THE examination under the microscope of the silver grain in a wet collodion negative alongside that of a film of gelatinobromide of silver shows that the size of the particles is approximately the same in the case of gelatine emulsion, e.g., as the Lumière blue-label. The silver grain reduced from wet collodion may be considerably larger than that of certain medium rapidity gelatine emulsions of commerce, that is to say it is larger than the Lumière yellow-label plate. Nevertheless, the definition of fine lines in a wet collodion is invariably better than that obtained on a gelatine plate of medium speed.

On the other hand, it is well known that, working with this type of emulsion, it is possible to obtain images of the same subject, the fineness of detail of which varies considerably according to the developer which is used; and, further, that the same developer with the same emulsion will give images of different degrees of fineness, according to the manner in which

it is employed. Further, it would appear that the size of the reduced grain of silver cannot vary sufficiently in order to explain the differences which are observed in the final result.

These facts would seem to point to the conclusion that the sharpness of detail does not depend only on the greater or lesser fineness of the grain of the plate, but arises from other causes which it seems interesting to investigate. Before embarking upon the study of the way in which the grain is formed in the films of gelatinobromide plates treated with a developer, we commenced by examining its formation in the wet collodion process. These experiments have a particular interest inasmuch as the films of collodion being extremely thin we eliminate the influence of the thickness of the film which plays a distinct part in the gelatine process. On the other hand, having ascertained that, according to the composition of the sensitizing salts added to the collodion, the size of the grain varies to a notable extent,

we were prepared to examine the influence which the size of the grain can have upon the final result. In making these experiments we reproduced the same size with a highly corrected lens and a line screen, such as that used by photo-engravers. Focussing was done on a transparent screen, and the image was examined with a microscope giving thirty diameters magnification. These experiments were made on five kinds of collodion:

1. With ammonium iodide.
2. With cadmium iodide and bromide.
3. With zinc iodide and bromide.
4. With a compound collodion.
5. With a sensitive commercial collodion.

Using these collodions, two negatives were made. The first was developed with iron and the second with pyro. A portion of each image was covered with a microscope covering glass fixed with Canada balsam and then photographed under the microscope at two enlargements—the first at 220 diameters in order to see the differences in the size of the silvered grain, and the second of thirty diameters in order to judge of the relative fineness of detail; lastly, on some of the negatives obtained at the enlargement of 220 diameters micrometric measurements were made in order to determine accurately the size of the reduced grain. The numbers which are given below represent in each case the mean of measurements, and they may be considered as of considerable accuracy. Proceeding in this way we obtained images in which the size of the silver grain varied in the proportion of 1 to 3.8.

Collodion.	Developer.	
	Iron.	Pyro.
	mm.	mm.
Ammonium iodide .....	.00166	.00140
Cadmium .....	.00205	.00106
Zinc .....	.00231	.00164
Daranne .....	.00154	.00154
Commercial, $\alpha$ .....	.00254	.00098
Gelatino-bromide of silver .....		.00304

There is nothing in these figures to lead us to think that owing to the extreme fineness of the particles their size could affect only in a small degree the sharpness of the images, especially when the latter are examined only by the naked eye or under a slight magnification.

The following observations are of interest from the practical point of view to wet collodion workers:—Salts of cadmium and zinc tend to increase the size of the image when a mixture of

acetic acid and iron is used in developing, but with the pyro-developer the silver deposit becomes finer. In the case of certain collodions the differences were very considerable, namely, .00231 to .00164 mm. for a collodion containing zinc, and .00254 to .000398 for the  $\alpha$ -collodion. The use of the pyro developer causes, for a given collodion, a considerable prolongation of the time of exposure necessary to obtain an image equal in intensity to that given by the iron developer. If these images be examined at an enlargement of thirty diameters it will be found that the sharpness of the lines is far from being in correspondence with the relative size of the silver grain. Thus the zinc collodion developed by iron gives a grain of the average size of .00231 mm., and an image which is comparable as regards sharpness with that given by a collodion containing iodide of ammonium likewise developed by iron, in which the size of the grain is only .00166 mm.

On the other hand, the image given by a collodion containing cadmium and developed by iron, the mean size of the grain of which is .00205, shows the fine lines less sharp than those given by the image with a collodion containing zinc. The defect of definition appears to result from a kind of growth, and the deposit of reduced silver takes place from the optical image, causing a want of homogeneity in the deposit. In the case of a cadmium collodion, if the use of pyro as a developer allows us to obtain a more homogeneous and much finer deposit, it is possible to prevent this spreading, which is the principal cause of the production of an unsharp image.

From the foregoing it seems that the principal cause of the good definition of a developed image does not lie necessarily in the greater or smaller size of the grain, but depends chiefly on how this latter is formed under the action of the developer. In collodion images we found that this alteration in the sharpness of the lines is caused by a growth which can only be lateral, the film being very thin and the deposit being entirely superficial. In the case of gelatine images the same phenomenon has necessarily much greater importance in consequence of the greater thickness of the sensitive film in comparison with that of a collodion plate, but the importance of the spreading action may vary with many circumstances, such as the thickness of the film, the greater or less rapidity with which the developers act, the presence of carbonate and caustic alkalies in the developer, etc. It is hoped to examine these various factors with the aid of microscopic sections photographed under the microscope.

M. MONPILLARD.

## THE ABERRATIONS OF PHOTOGRAPHIC LENSES.

The Tenth Traill-Taylor Memorial Lecture.

### II.

#### Astigmatism and Curvature of Field.

The effects of these two aberrations are proportional to the aperture and to the square of the angular field. It is usual to express the effects in terms of the positions of the 2 line foci corresponding to a point not on the axis.

In Fig. 6 the focus for the rays which remain entirely in one plane is at  $C_1$ , the other line focus at  $C_2$ . The beam of light will meet the focal plane, in the ellipse shown in section in the same figure. Curves may be drawn through all the points similar to  $C_1$  and  $C_2$ , and in the case we are considering will be very nearly circles. If  $C_1$  coincide with  $C_2$  there will be no astigmatism, and if  $C_1$  and  $C_2$  are at equal distances on either side of the focal plane, there will be no curvature of field, since the best average definition lies on the focal plane.

It can be proved that the curvature given by Petzval's expression

is that of the curvature which passes through points on the opposite side of  $C_2$  from  $C_1$ , and at a distance  $= \frac{1}{2} C_1 C_2$ . Thus the expression  $\Sigma \frac{F_1}{n_0 n_2}$  gives the curvature for points where the section of the beam has diameters in the ratio of 3:1.

Considering these aberrations as producing errors on the focal plane, the image due to a zone of aperture ratio  $A$  at an angular field of  $\delta$  will be an ellipse, whose axes are

$$(3k + p) A \tan \delta f,$$

and

$$(k + p) A \tan \delta f$$

where  $k$  can be calculated for any system, and  $p$  is the Petzval expression multiplied by the focal length.

When there is no astigmatism  $R = 0$ , and when there is no curva-

ture of field  $2k + p = 0$ . In the latter case the axes of the ellipse on the focal plane are

$$\frac{1}{2} p A \tan^2 \theta f,$$

and

$$-\frac{1}{2} p A \tan^2 \theta f.$$

These diameters can be made sufficiently small, even though  $p$  is

Fig. 6A.

Scale =  $\frac{1}{10}$  mm  
Fig. 7.

not very small. Taking  $f = 8''$  with an aperture of F 5 and a semi-angular field of 30 deg., the diameter

$$= 8 \times \frac{1}{10 \times 4} \times \frac{1}{2p} = \frac{p}{10}.$$

If the standard of definition be 1.250 inch, the greatest value of  $p$  is 1.25 (or 1.15).\*

It will, however, be shown later that, provided the other aberrations are of suitable amounts, this value of  $p$  may be increased four times.

When smaller apertures and fields are considered, this value of  $p$  may be much increased. The normal value of  $p$  is about two-thirds when the power does not arise from separation, and this is, approximately, the limiting value for a lens to give our standard of definition with an aperture of F 6, a semi-angular field of 20 deg. and a focal length of 4 inches.

Thus we arrive at the conclusion that Petzval's condition need only be satisfied very approximately in systems of reasonable aperture and field, and we shall see that when there are aberrations of higher

Fig. 8.

Fig. 9.

order in astigmatism and curvature of field that a departure from Petzval's condition is necessary to secure the best possible results. Still, the Petzval expression has its uses, and, from the value of this function, we can predict the field that we may expect to cover, provided the other aberrations are suitable.

\* These expressions should be multiplied by  $\cos^2 \theta$  and  $\cos^2 \theta$  respectively, i.e., for 30 deg. factors of .65 and .75 respectively.

### Astigmatism and Curvature of Field of Higher Order.

These defects depend on the aperture and the fourth power of the angular field, and are present to a certain extent in all lenses. The focal plane effects are similar to those of ordinary curvature and astigmatism, but may be of the same or opposite sign. Where practi-

Fig. 10.

ticable, values of first order aberrations must be chosen to balance out these defects as far as possible.

In Fig. 7 the effects of the aberrations of the experimental lens system are shown.

The distances in Fig. 6 represent diameters of discs on the scale of 1.11 to that of the diagram. It will be noticed that Petzval's

Fig. 11.

condition is strictly fulfilled, since  $C_1 = 3C_2$ , but that there is no correction of astigmatism or curvature of field.

The curve  $C_1$  has been so chosen that it comes back to the focal plane at 21 deg., i.e., that one diameter of the spot vanishes for this angular field. In order that the curve  $C_2$  should come back to the plane at this same place, it would be necessary (supposing the other aberrations unaltered) to make Petzval's expression = power of lens.

Fig. 14  $\times 10$  times.

The very considerable change of form that this would require would very considerably modify the other aberrations, but it is evident that a modification of this system in the direction of departing from Petzval's condition would be very desirable. It will be noticed in the case of the curve  $C_1$  that the effect of the second order aberration is to reduce the maximum value of the ordinate of this curve to one-quarter of the value of the first order aberration at the extreme edge

of the field, or to one-quarter of the corresponding value of the second order aberration.

*Spherical aberration for oblique field.*—In addition to the modification of the spherical aberration for the oblique field that is indicated above, there are defects which arise from an aberration of higher order. It is found that even when the spherical aberration is well corrected for the centre of the field, and there is no astigmatism or curvature of field for small apertures, an effect of bad definition may arise from a cause analogous to spherical aberration. This effect varies as the cube of the aperture and the square of the angular field.

Fig. 12.

There are two separate constants which give rise to the aberrations shown separately in Figs. 8 and 9, and in combination in Fig. 10.\*

These aberrations have a very important bearing on the performance of objectives, and are one of the chief causes of discrepancy between calculated and measured values of the astigmatism and curvature of field in photographic lenses. The effect of these aberrations may be to improve the definition on the focal plane by compensating the effects of other aberrations. In particular, the first of these two aberrations tends to mask curvature of field.

In some anastigmats two positions of good focus for horizontal and vertical lenses are sometimes found; this effect is also due to oblique spherical aberration. Again, we frequently find this aberration in

Fig. 11 represents the double ellipse, which corresponds to these aberrations alone for the same aperture ratio and field as above. And just as the oblique spherical aberration depends on two constants, so this coma will depend also on two independent constants. The effects of these comatic aberrations will be to produce a considerable modification of the coma figures for oblique fields.

In order to obtain the combined effect of all these aberrations, we must obtain their effects for the desired aperture and angular field, and add together all the displacements corresponding to each point on the aperture, taking separately the displacements radially out-

Fig. 13.

wards and those at right angles (In the figures the vertical and horizontal displacements.)

It is at once evident that the numerous aberrations may lead to very curious figures; some actual images formed by a similar lens are shown in Fig. 12. The images were photographed with white light on the actual focal plane of the lens, the objects being small circular apertures.

Fig. 13 shows images of small apertures obtained by using a similar lens for a distant object; these images are magnified four times in the original photograph.

Fig. 14 shows images of a small aperture by the system formed by using two such lenses symmetrically placed; the greater part of

Fig. 15.

Fig. 16.

Fig. 17.

Fig. 18  $\times 5/3$ .

lenses which have been calculated by the aid of formulae, which give the positions of the two focal lines formed by narrow oblique pencils; the curves for these focal lines will frequently fail to give a correct idea of the performance of such lens systems. The curves given in Dr. von Rohr's classical work on photographic lenses were obtained in this way, and in some cases give rather an unfavourable impression of those lenses which have been obtained empirically.

Just as these two aberrations arise from oblique spherical aberration we find two aberrations which arise from oblique coma.

the coma effects are eliminated. The various images were magnified ten times in obtaining the original photographs.

In Fig. 15 the images formed by the single member above are shown; the stop is a small patch stop, a zone of 3 mm. width at F. 12.\* The figures indicate that in this particular case the astigmatism is not quite corrected.

In the next photographs (Figs. 16 and 17), similar results are given for a different position of the stop. The combined effects of astigmatism are apparent in the figures. The lens whose aberrations have

\* The scale of Fig. 10 is larger than that of Figs. 8 and 9.

\* The white parts of the image are due to the cross-pieces of the patch stop.

been calculated above is used for Fig. 18, which shows the image of a small object when a half zone of 20 mm. diameter on the stop is used, but to isolate the points separated small apertures are used instead of the whole zone (these apertures are 1 mm. in diameter). Two such photographs are shown, differing only in a slight adjustment of the plate. They agree, within the limits of reproduction, with the results of the calculated aberrations. The centre of the stop corresponds to the spot outside the ring. In this case the image was not magnified, but taken on the original focal plane; for clearness it has been slightly magnified.

In addition to the aberrations mentioned above, the lens may give distorted images due to two aberrations, depending on the third and fifth powers of the angular field. When these are in opposite directions they tend to balance as regards the more oblique field, and in some cases straight lines appear curved, but become straight towards the edge of the field, and even curved in the opposite direction.

I trust that this account of the various aberrations of photographic lenses may enable workers to express in numerical form the results of measurements of photographic lenses or the results of trigonometrical calculations. It will, I hope, lead to some generally accepted system of stating the performance of photographic lenses in terms of the size of the image on the focal plane, perhaps in the form of a photograph like those which appear in Messrs. Beck's paper read to your society.\* In any case it will remove some of the difficulties of reconciling theory with practice, and thus tend to further the scientific study of photographic lenses from both points of view.

S. D. CHALMERS.

#### THE KEEPING QUALITIES OF PERSULPHATE REDUCERS.†

FROM experiments made some years ago on the persulphates it was shown that simple solutions of these important salts of the photographer possess very considerable stability, a fact which was further confirmed by fresh analytical determinations. Since then Mr. H. W. Bennett has recommended a new reducing bath in which persulphate figures in conjunction with sodium sulphite and sulphuric acid. According to the claims of the author a bath prepared in this way acts better and keeps in good condition for a much longer time. As it is difficult to understand why a reducing substance such as sodium sulphite should figure in this solution, we have undertaken observations with a view of finding whether the bath recommended by Mr. Bennett possesses any advantages over the simple persulphate solution, and we have further made comparisons on the keeping qualities of plain persulphate solutions, and of those prepared in accordance with Bennett's formula. We used three different brands of ammonium persulphate, namely, No. 1, of German origin, containing 53.2 per cent. persulphate, another of Lumière which we had in stock for five years, and which contained 47.6 per cent. persulphate, and a third made by Kahlbaum containing 96.8 per cent. persulphate. The solutions were made in cold distilled water and stored away from light. The analyses were made by titration with iodine, that is to say, by estimation of the iodine liberated on mixing the persulphate solution with potassium iodine solution at a temperature of 60 degrees C. In preparing the solutions according to Bennett's formula, it is noticed that sulphurous acid is liberated by the acid in the persulphate, and remains for some time in the solution. But after three or four days no further odour of sulphur dioxide can be detected, the substance having been oxidised by the persulphate, as can be proved by the partial destruction of this latter body. It was found by calculation that the quantity of persulphate destroyed corresponded exactly with that required for the oxidation of the sulphite in the solution. In these analyses regard was paid to the quantity of sulphurous acid which serves for the exact calculation of the persulphate. The action of all these solutions on the negative is almost exactly the same, and we found no difference between the simple persulphate solution and that of Bennett in the course of tests of which two halves of one and the same negative were submitted to these distinct reagents. We thus came to the conclusion

that while this solution has no advantages in point of action on the negative it is distinctly less permanent than the simple solution.

...	8'56	8'43	—	—	—

The added sulphite reduces only a portion of the persulphate, being converted into sulphate, and thereby augmenting the proportion of this latter substance which already exists in the commercial persulphate. In the case of the latter solutions, therefore, the final result was a simple persulphate solution containing slightly less persulphate and a slightly greater proportion of acid. The addition of acid or alkali exercises a slight influence on both the permanency of the solution and on its action on the negative. Alkali to some slight extent affects the results of the analysis since it absorbs a small proportion of iodine, and the solution therefore appears to be slightly weaker in iodine than is actually the case.

Ammonium sulphocyanide, which, as it seems to us, exerts a favourable action on the solution of the silver salts, is, however, injurious in a persulphate solution, since it immediately exerts a distinct reducing action which proceeds until the persulphate is completely destroyed. From these facts it is plain that on one hand the simple aqueous neutral or acid solution of ammonium persulphate keeps in good condition for at least a couple of months if prepared with distilled water and protected from light, and, on the other hand, that the Bennett formula is open to objection as regards permanency and has no other advantage. Further, that an addition of a solvent of the silver salts, such as ammonium sulphocyanide, though theoretically advisable, acts in too high a degree as a chemical reducer of the persulphate to be of any practical service.

R. NAMIAS.  
ADOLPH BASCHIERI.

**CINEMATOGRAPH FIRE.**—A cinematograph fire occurred last week at an entertainment which was being given to 800 children at Skewen, near Neath. The flames shot up sixteen feet, and damage was done to the amount of £200. The timely action of a police-sergeant prevented a panic, and the children were marched safely out of the building.

† From "Das Atelier."

## THE OIL PROCESS.

At the Blenheim Club, on the 5th inst., Mr. G. E. H. Rawlins gave a practical demonstration of the oil-printing process, which was followed with the keenest interest. Mr. Rawlins recalled a similar demonstration which he gave at the old Camera Club in 1904, and said since then a great many had taken up the process and worked it. Various improvements had been proposed, but he chose his own personal methods of working. The beauty of the process was that it was capable of great diversity of treatment. He did not claim to be the parent of the process, which had its birth in the fifties, but he worked it out himself before coming across Poitevin's patent of 1855. Since his (Mr. Rawlins') last demonstration arrangements had been made for suitable materials to be placed on the market. He personally worked out a paper which he considered most suitable. It was quite possible to prepare paper and pigments at home, but they required messy and laborious operations. A coating given to the paper, provided it be fairly thick, of Nelson gelatine might be used for a basis in the process, but that was not so satisfactory as paper cut by machinery. Materials, however, were a minor matter. Almost anybody could produce a literal straight print, which rendered accurately the gradations of the negative. It was when they came to controlling, amplifying, and improving that the oil process particularly appealed. Like the gum process, it was capable of very considerable alteration in tones and values. In the gum process, however, all that it was possible to do was to wash away portions of the image, and once those portions were washed away they were gone for ever. The only way was to re-coat, re-develop, and reprint with all the attendant risks. Mr. Rawlins then proceeded to demonstrate the oil process on a piece of gelatinised paper, which had been immersed in a bath of bichromate of potash. The paper was not sensitive until it was dry. When dry, it was printed under a negative in the usual way, when an easily visible image was obtained. The basis was then immersed in water, and when the bichromate was all removed the relief of the high-lights which stood above the levels of the shadows was, to a greater or less extent, a measure of the water which the high-lights had absorbed. Mr. Rawlins placed the wet print on a sheet of plate glass and gently rubbed off the surface water with a soft rag. He then explained how the pigment was applied, using an ordinary painter's palette, and lightly applying microscopic quantities on a brush to the print, which almost directly showed a picture of a country cottage. Having shown how easily a perfectly straight print might be obtained, he showed how the values might be altered in various parts, the latent image being unaltered throughout. The pigment might be removed from the various patches and the patch brought back again wholly or partially by the "hopping" action with a brush of the finest hog bristles. To wholly obliterate the image the brush must be more firmly applied with a "dabbing" action. It was necessary the whole time to have the gelatine quite moist with water, but no water should get on the surface of the print. Mr. Rawlins said he attached a good deal of importance to the retention of the photographic drawing. It had been said that oil printing was monochrome painting on somebody else's drawing, and to a certain extent that was incontrovertible, but the so-called painting was, after all, only a very direct and facile method of controlling the relative values of portions of the picture. It was very much the same as working with pencil or chalk on the back of a negative, only that much less safe and easy, and in working on the positive the artist could see exactly what he was doing. Mr. Rawlins considerably changed the appearance of the cottage on which he was working from time to time with his brushes, showing that the process afforded control to an almost unlimited extent.

## THE LATE MARTIN JACOLETTE.

We announced last week the death of Mr. Martin Jacolette, which occurred on the 2nd inst. in his fifty-eighth year. The deceased gentleman was the son of a well-known miniature painter and daguerreotypist in Dublin, and was himself practically acquainted with the working of the daguerreotype process. In business as a photographer at Dover for many years, in 1890 he opened a business at South Kensington, and the two businesses have been carried on simultaneously until the present. From the institution of the Professional Photographers' Association in 1901 Mr. Jacolette took a leading part in its management, and occupied the presidential chair

last year. He was a member of the Royal Photographic Society, and had on more than one occasion served on the Selection Committee of the exhibition. He was a quartermaster-sergeant in the Middlesex Yeomanry, and was also connected with several masonic and other organisations. Of a most genial nature, he made a large circle of friends, by whom his loss will be most sincerely mourned. The funeral took place on Thursday last at the Kensington Cemetery, Hanwell.

Following these words of lament for our departed friend, we may quote a letter sent from Mr. Lang Sims, who, as treasurer of the Professional Photographers' Association, was continuously working in collaboration with the late Mr. Jacolette. Mr. Sims writes:—"Although it would take a better hand than mine to do full justice to his memory, I feel I can say a word or two regarding him which will be acceptable to his many friends. His loss will be greatly felt by his colleagues upon the committee of the Professional Photo-

The late Martin Jacolette, ex-President of the Professional Photographers' Association.

graphers' Association. His breezy style, earnest and energetic manner endeared him to us, and so far gained our respect, that when the presidency was offered him we felt that he would worthily follow in the footsteps of his predecessors. It is well known in the profession our choice was fully justified, for he entered heart and soul into the work, never sparing himself when the interests of the Association demanded his attention. He was, in temperament, quite the opposite to the late William Grove, who had a gentle and retiring disposition; yet both will be equally missed and mourned for their loyalty and comradeship. The loss of these two men in so short a time is indeed a sad blow, but they have left behind them the record of work well and unselfishly done, and an example that others equally high in the profession might, and should, follow. The fight to rouse the rank and file from deadly apathy into brisk life and union was, at the outset, no easy matter; but Martin Jacolette was never disheartened, and always advocated 'fight on,' and the present sound position of the P.P.A. is practically due to that policy. He is gone, but left behind is an affectionate remembrance exhilarating and comforting."

**AUTOCHROME VARNISH.**—A dammar varnish, made with carbon tetrachloride, is being sold by a German house to Autochrome users.

### A PROFESSORIAL CHAIR OF PHOTOGRAPHY IN GERMANY.

THE Technical High School of Dresden has decided to found a Chair for photography, and its occupant is to be distinguished with the title of professor. Photography has always been more or less recognised in the various scientific departments of German universities, and much care and attention has been given to the perfecting of instruments for astronomical, medical, and physical research, but this is the first occasion on which it has been raised to the dignity of a professorship, and there is every reason to believe that the example will be followed in other centres of learning. The object of this professorship is not only to encourage and promote the development of scientific photographic instruments, but also to train and equip men for the various industrial branches of the profession. Dresden has long been recognised as the centre of photographic activity in Germany. Besides a considerable army of enthusiastic professional and amateur photographers, it possesses one of the largest photographic manufactories in the country. A considerable number of workers are employed in the manufacture of all kinds of cameras, plates, films, and papers. This factory includes an egg-conserving department for the supply of albumen, cabinet-makers' workshops, a fittings factory, and a repairing department. Of equal importance is the number of industrial institutes for the production of photographic pictures and the various art productions produced by means of photography, which branches have always been especially fostered in Dresden. These have not been without their influence on the scientific and the artistic world, and the introduction of the picture postcard, of which very large numbers are manufactured in Dresden, has added to the importance of this branch of the industry. In all these departments and in special studios fitted out for the purpose a large number of men are kept constantly employed working out improvements for cameras and in chemical research and experiments for perfecting those materials directly used in the taking of photographs. For a long time the growing necessity has been felt for a suitable centre under the direction of a man or staff who is a specialist in chemistry, physics, machine and fittings technique, and thoroughly understands these in their connection to applied photography. His duties will be to direct these experiments and researches along lines likely to lead to the best results. It is in response to this demand that the Technical High School of Dresden has broken with tradition and established the chair for photography.

One of the leading spirits in this movement is Prof. Kröne, whose valuable work for photography has been so widely recognised that he is now looked upon as the greatest authority on photographic matters in Germany. He is now about to retire from his official position, and the introduction of this department for practical photography under a scientific leader is looked upon as a fitting climax to his long and distinguished career. We are promised further particulars concerning this interesting departure about the time of the opening of the forthcoming Dresden International Exhibition of Photography.

THE "Prism" for November contains, among other interesting features, a short article dealing with the use of the telescope in certain classes of survey work. The booklet may be obtained by sending a penny stamp for postage to Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

MESSRS. J. H. DALLMEYER, LTD., inform us that they have recently appointed several new wholesale agents for their lenses and apparatus abroad. In the United States, Taylor, Taylor, and Hobson, Ltd., of New York, are sole agents for the world-famous Dallmeyer patent portrait lenses; whilst Burke and James, of Chicago, hold the selling rights for the Stigmatic, Adon, telephoto, cinematograph, and other lenses. A new company, J. H. Dallmeyer A.G., with its headquarters in Berlin, has been formed further to develop the trade in Germany, Holland, Switzerland, Denmark, Norway and Sweden. Mr. Leopold Loebenstein, of Vienna, is wholesale agent for Austria-Hungary, the Balkan States, and Egypt. It may be worthy of note that British lens manufacturers, like British dry-plate manufacturers, are able to hold their own in foreign markets in face of high tariff walls and fierce competition. In the United States the duty alone amounts to 45 per cent. of the value of the goods, whilst Germany is the home of the firm's keenest competitors.

## Exhibitions.

### NORTH LONDON PHOTOGRAPHIC SOCIETY.

THE following is the list of awards made by Mr. Furley Lewis:—Class B—63, "Early Morn," W. A. I. Hensler; 79, "Sunlight, Haarlem Cathedral," H. P. C. Harpur; 52, "Moses Melchoir," Oscar Hardee. Class C—103, "Fruit and Wine," H. J. Comley. Class D—127, "Arthur J. Gear, Esq.," C. Wille. Class E—171, "Strength and Weakness," C. H. Roberts. Extra Plaque—180, "Denham," C. H. Madden. Class F. No plaque awarded. Class G—223, "The Village Church," C. H. Connolly; Class H—260, "A Brown Study," W. F. Rippin. Hon. Mention—268, "The Depth of the Wood," A. W. Green. Hon. Mention Class L—"Hampton Court," E. H. Ingleton. No plaque awarded. The President's silver award is given to—223, "The Village Church," C. H. Connolly.

### NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

FOR nearly twenty years has the North Middlesex pursued a course inconspicuous and almost uneventful prosperity. Keeping itself to itself, and seeking the photographic welfare of its members, it has not been heard of one-half as much as many another less solidly established body. Its aim has evidently been to develop its own resources, and to this tradition it has been true in the management of its annual exhibition, to which it admits no one outside its membership. It must be acknowledged that in this policy it has shown itself wiser in its generation than other bodies of like responsibilities, for its members have distinguished themselves at exhibitions, and the society has attained a local habitation and a name upon the heights which border London on the north which bids fair to survive the rise and fall of other organisations. Our report, therefore, of the annual exhibition of the society, held for three days last week, must necessarily be of limited interest, except in its indication of policy, which has proved notably successful, and has led to the creation of a collection of pictorial photographs which in its entirety is of considerable merit, and includes not a few really excellent achievements. Among those members specially deserving of mention for the artistic or technical merit of their work are Messrs. Chas. Beadle, M. F. Black, Louis Dick, H. W. Fincham, Douglas P. Fox, A. H. Lisett, J. C. S. Mummery, J. F. Nisbett, W. Pringle, E. C. Ridge, H. Stuart, and A. J. Woolway. The exhibition included a very good showing of Autochrome transparencies, in which the work of Mr. Woolway and Mr. Nisbett calls for special mention. The award goes to a single transparency by Mr. Nesbit, but Mr. Woolway undoubtedly shows the better collection. The awards, made by the judges, Mr. E. T. Holding and Mr. J. C. S. Mummery, were as follows:—

No. 1, "The Hospital," W. Pringle; 22, "A Corner of the Cloister," H. W. Fincham; 30, "A Bend in the Road," H. Stuart; 41, "The Antiquary," C. A. Morgan; 57, "A Lone Land," Louis Dick; 97, "Portrait," M. F. Black; 132, "Autumn," E. C. Ridge; 157, "A November Day—St. Paul's," D. P. Fox.

Lantern Slides—218, "Ely, from the North-west," H. W. Fincham; 263, "Dolly," M. F. Black.

Autochrome—323, "Near Hollington," J. F. Nisbett.

Hon. Mention—2, "A Farm Road," Louis Dick; 27, "A. H. L.," M. F. Black; 34, "Miss E.," M. F. Black; 37, "Granada Cathedral," W. Pringle; 48, "In the Lea Valley," H. T. Nobbs; 63, "New Fairy Tales," C. A. Morgan; 96, "Evening on Loch Linnhe," C. Beadle; 135, "An Old Gateway," M. F. Black; 154, "The Calm of Evening," A. G. Lawson.

Lantern Slides—221, "A Corner of the Cloister," H. W. Fincham; 250, "A Lone Land," Louis Dick; 253, "Glacier Depths," R. H. Maxton; 257, "Nest of Moorhen," W. Jackson; 264, "The Pond," H. C. Turner.

Autochromes—318, "Dresden Ware," A. J. Woolway; 326, "Chrysanthemums," J. F. Nisbett.

GERMAN PHOTOGRAPHS IN PHILADELPHIA.—"The Bulletin of Photography" has recently held a special exhibition of German photographs, arranged by R. Dührkoop, of Hamburg. The collection consisted of about two hundred pictures by the leading photographers of Germany, Austria, and Switzerland. They will be exhibited in the galleries of the Drexel Institute, Philadelphia, from November 27 to December 7.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between November 25 and November 30:—

**CINEMATOGRAPHS.**—No. 26,107. Improvements in cinematographs. Charles Dupuis, 52, Chancery Lane, London.

**CINEMATOGRAPHS.**—No. 26,122. Improvements in or relating to cinematographs and like apparatus. Benjamin Jumeaux, 111, Hatton Garden, London.

**CAMERA CASES.**—No. 26,206. Improvements in carriers or knapsacks for cameras, parcels, and the like. Charles Lavender, Imperial Chambers B., Colmore Row, Birmingham.

**TIMING DEVELOPMENT.**—No. 26,279. Watch for recording the correct periods required in the development of photographic pictures with various chemicals. Robert Charles Pickering Richards, "Rondebosch," Sandown, Isle of Wight.

**PRINTING PAPER.**—No. 26,445. Method of producing paper to be used as photographic or blue print paper and the like. Max Roth, 40, Chancery Lane, London.

**CINEMATOGRAPHS.**—No. 26,487. Apparatus for taking and reproducing cinematographical or moving pictures. Otto Gergacsevic and Ernest Franzos, 5, Corporation Street, Birmingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**MULTIPLE PORTRAITS BY MIRROR.**—No. 8,957. 1907. The invention consists of two flat mirrors, which are placed vertically and at an angle to each other. The abutting edges of the mirrors are carefully bevelled so as to bring the reflecting surfaces accurately together at the origin of their enclosed angle and so produce a continuous reflecting surface. The mirrors are preferably high enough to reflect a full length figure, and are supported and held by angle pieces upon a platform mounted upon castors. The mirrors are relatively inclined at an angle of 72 degrees or thereabouts, and in operation the person or object to be photographed stands upon the platform, within the angle made by the mirrors. Drapery or other screens may be used, so as to jut out from the outer edges of the mirrors, thus providing a plain, even-tinted background, extending across the picture when photographed. If a photograph be taken looking into the angle, five images of the object are obtained, which, in the case of a person posing side face to the camera, would consist of the non-reflected side view, and reflected front view, back view, three-quarter back view, and three-quarter front view. James Beckett Shaw, 91, Blantyre Road, Liverpool.

**STEREOSCOPIC TRIPOD HEAD.**—No. 10,695. 1907. The invention consists of a sliding block, having side plates turned in at bottom and fitting in grooves in the base plate, which latter is attachable

to a tripod. The slide is fitted the clamping screw B, to secure it to the tripod, the hole C is made right through the base plate to affix the camera to the sliding plate. One end of the sliding plate D carries the pivoted locking lever E or other arrangement, and its enlarged end, head, or lug e, when in the locking position drops in the longitudinal groove e', in the base plate A, which runs from the left hand to the hand hole e<sup>2</sup>. This latter serves a double purpose primarily for clearance for head of thumbscrew d, and reaching to the end to provide for fall of the locking lever E. When in each desired position the lever also rests in one of the right angle grooves or slots F, F<sup>1</sup>, or F<sup>2</sup>, which denotes the inter-ocular distance of the stereoscopic pictures. In the upper face of the sliding plate D are indiarubber studs G, projecting slightly above the surface to prevent any lateral movement of the camera, H. The movement of the sliding plate D supporting the camera from the first to the second position from right to left is denoted by the arrow.

When an intermediate position is desired the sliding plate is moved to the slot F<sup>1</sup>, shown in dotted line. The instrument having the combination of an upper plate always in direct and constant contact with the lower plate is well adapted to take or obtain two views (right and left) one after the other at the proper distance apart (it may be the regulation distance of three inches) or otherwise. Ernest George Brown, Brighton Villa, Stoneycgate Road, Leicester.

**DAYLIGHT DEVELOPMENT.**—No. 12,249. 1907. The apparatus consists of a closed chamber, in which is a developing tank and a fixing tank, the latter provided with shelves and pockets for the reception of the plates, one by one, from the development tank. Arthur Clarence Hayden, 204, Howard Street, Brockton, Massachusetts, U.S.A.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

**PROJECTION BANDS.**—No. 25,165. Metallised photographic bands for projection by reflection. Dupuis.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Right Way to Pack a Negative.

Safe packing (writes Mr. W. J. Casey, of Raines and Co., in "The Photographic News") is only a question of "knowing how." To carry a  $\frac{1}{2}$ -plate negative, a box with its sides  $\frac{3}{16}$  in. thick, and top and bottom  $\frac{1}{4}$  in. in thickness is necessary. Around the negative must be placed something that will serve to prevent damage by vibration. My own firm uses "wood-wool" packing—and our regular customers save that in which we return their negatives for their next order. A word of caution is necessary as to the special need for care when packing different-sized negatives in one box. They must be so placed that the smaller negatives do not exert any uneven pressure on the larger ones. If, for example, a  $\frac{1}{4}$ -plate has to be packed with two  $\frac{1}{2}$ -plates, it is obvious that if packed in between them it will at once act as a fulcrum on which the negative above can see-saw. And see-sawing is most decidedly not advisable where glass is concerned. The best plan is, under such circumstances, to place the two half-plates film to film, and then, on top of them, a piece of card of the same size. The weight of the  $\frac{1}{4}$ -plate negative resting on the card is then distributed evenly over the  $\frac{1}{2}$ -plates.

### Local Glazing of Bromide by the Bromoil Process.

By adapting Mr. Welborne Piper's latest Bromoil process (writes Mr. T. H. Greenall in "The Amateur Photographer") I have been able to obtain bromide prints to which can be applied a varnish in the same way as the pigments are applied in oil printing, and which will take the varnish on the image only, and not at all on the highest lights, thus marking a distinct advance in bromide work. The fixed and washed bromide should be allowed to dry, otherwise blisters may appear in subsequent operations. It should not, however, be alumed or treated in a fixing bath containing alum. It is then

to a tripod. When the slide is moved to either position it is locked for taking the first or second pictures or views. Two plates of wood or metal are made of the desired width, length, and breadth to suit an ordinary or monocular camera. In the under side of the base

bleached in Mr. Piper's bromoil bleaching solution, of which the following is the formula:—

Concentrated ozobrome solution .....	4 parts.
10 per cent. potash alum solution .....	4 parts.
10 per cent. citric acid solution .....	1 part.
Water, to make .....	20 parts.

I have used two-thirds this quantity of alum with advantage. In about two minutes the black image should be completely changed to a faint brown one. The print is then washed, and either treated with sulphide solution, as in ordinary sulphide toning, or re-developed, in which case the final image will be black. The sulphiding solution consists of:—

10 per cent. solution of sodium sulphide .....	25 minims.
Hydrochloric acid (one in five solution) .....	5 minims.
Water .....	2 ozs.

NOTE.—The hydrochloric acid must be added at the last moment before using, and fresh solution mixed each time.

The alternative re-developing solution must be fresh, and consist of:—

Amidol .....	2 grs.
Sodium sulphite .....	20 grs.
Water .....	1 oz.

After either sulphiding or re-developing, the print is just rinsed and then placed in sulphuric acid, diluted, 1 oz. in 20 ozs. of water, as in the bromoil process. (N.B.—Add the acid to the water and allow to cool before using.) In this bath the print is allowed to soak for twenty minutes or longer, and is then washed for ten to twenty minutes and dried; or it may be taken at once for varnishing. The varnish consists of a few drops of Japan gold size and a touch (about one-fifth the quantity) of raw linseed oil, and should be mixed with an old table knife on a piece of glass.

#### The Krayn Screen-plate.

Experiments, which Krayn himself is directing (writes Dr. S. E. Sheppard in "Focus"), are in progress with a view to increasing the fineness. Filters of the Lumière type can already be reached by cementing the original line screens so that the lines cross, and cutting the composite block perpendicularly, but line filters offer the advantage that copies can be readily produced. It is hoped to prepare a material which shall supply not only a positive transparency by reversal after development, as in the Autochrome process, but a positive image by reflected light, as in paper images, the substratum being, however, a celluloid film, matt and opaque white. It is stated that the blue dye is so darkened that no compensating yellow filter is required in exposure, and that an emulsion capable of being worked in a deep red light will be used, of sufficient rapidity for use in the cinematograph. The most imposing feature of the process is the certainty with which large quantities of the material can be prepared. When 1,000 kg. of celluloid of each colour has been prepared and spectroscopically tested, there is nothing to prevent the rapid production of some 3,000 kilos of ready filters, a rate of production unequalled by any of the other processes, and permitting far greater sizes to be reached. It is expected that the plant will be ready to deliver commercially in February next; the films will be supplied direct to plate-makers, to coat with their own emulsion, by the "Deutsche Raster-gesellschaft."

## New Books.

"Wellcome's Exposure Record and Diary, 1908." London: Burroughs, Wellcome, and Co. 1s.

Several new features appear in the 1908 edition of this well-known pocket volume. A wall table for warm tones on lantern slides by development with the "tabloid" Rytol and other preparations is presented as a loose inset. The text of the "Diary" is on the lines of the nine previous issues, but contains one new table of exposures in outdoor night photography, another of plate speeds, and a third of exposures in interiors. The popular exposure calculator has undergone no further modification, and may certainly be regarded as the acme of convenience and comprehensiveness among such aids to the correct exposure of plates.

"Home Life of Marsh Birds." Photographed and described by Emma L. Turner and P. H. Bahr. London: Witherby and Co. The above is issued as a special "photographic" issue of "British

Birds," a monthly magazine devoted to the study of the birds of Great Britain. It is a volume of sixty pages, containing thirty plates from photographs by the authors. Each bird is the subject of a few notes on its habits and haunts, and the authors relate their heroic experiences in photographing their timid subjects with a good deal of gusto. Incidentally, they show a nice sense of the humour of bird life, which, on its domestic side, is not always above reproach.

"Deutscher Camera-Almanach, 1908." Edited by Fritz Loescher. Berlin: Gustav Schmidt. Mk. 4.

We will not deny that the mixture which Herr Loescher offers is quite to our liking. He reproduces some 150 examples of the modern pictorial photography, but he confines what he has to say about them to an article (of a few pages) entitled "What the Pictures Have to Say for Themselves." Wise man, he lets us take a good look at his pictorial wares before we come to where he discourses in praise and otherwise. For text therewith to help out the pictorial contents, we find twenty odd articles on enlarging, moonlight photography, picture postcards—and even of anastigmats. Well printed on good art paper in a black ink throughout, the photographs get as good a showing as can be done in half-tone printing. The book is as good as any we can name of German origin.

"Penrose's Pictorial Annual, 1907-8." Edited by William Gamble. (Vol. XIII.) London: A. W. Penrose and Co. 7s. 6d.

The reproductive crafts once more have a very full representation of their various branches in the current issue of the "Process Year Book," or, to give it the name which the publishers now adopt, "Penrose's Pictorial Annual." The thirteenth volume, published within the past few days, is distinctly bulkier than its recent predecessors, due apparently to a greater number of plates and supplemental illustrations rather than to an increase in the text pages. The cover, to which Mr. Gamble has in the past devoted a good deal of care, is this year designed by Mr. Charles E. Dawson, and though excellent as a piece of design, is far less effective than the covers of some recent issues, notably one of a few years ago by Mr. Littlejohn. The title page, printed by the Aerograph Co. by their spray printing machine, is an excellent technical example of this ingenious method, due to the inventive genius of Mr. A. L. Burdick, though no one will be convinced, we expect, of its particular suitability for the purpose for which we find it used. For all kinds of decoration in light washes of colour the aerograph is without a rival, but as a substitute for typographic display it does not show to good advantage, and it certainly forms a jarring contrast with the strong and dignified frontispiece to the Year Book which faces it in the shape of a heliotype reproduction from an old copper engraving. When we come to the text pages we find a collection of articles containing a number of items of considerable photographic interest, such as that by Mr. E. T. Butler on "A Single Exposure Three-Colour Camera," on "A Preservative Case for Platinum Paper," by S. K. Lawton, and on "Photographing Lace," by Ernest Marriage. Colour-photography figures among the contributions from various writers, Mr. E. J. Wall discourses on "Coloured Light for Colour Work," Dr. R. S. Clay on "Chromatic Aberrations of the Eye in Relation to Three-Colour Photography," M. Gravier writes also on "Theories of Vision in Reference to Colour Work." The screen-plate processes are dealt with by two of the inventors now before the public, namely, Mr. J. H. Powrie, who writes of the Warner-Powrie process, and M. Alcide Ducos du Hauron, whose characteristic contribution relates to the long-promised "Omnicolore" plate. Dr. J. H. Smith has a note on the making of paper prints on bleach-out paper from Autochrome plates, and an equally characteristic paragraph by Mr. F. M. Sutcliffe deals with the fading of colour prints. These items are selected only from those of direct photographic interest. The major portion of the text relates to the technical and business sides of the process trade, and includes among its contributors such well-known writers on these topics as Messrs. A. J. Newton and A. J. Bull, Arthur Payne, N. S. Amstutz, J. S. Sunderland, Harold Hood, Howard Farmer, H. Hands, F. T. Corkett, and C. G. Zander. The contributions of these and other authors occupy nearly 200 pages of text, but are responsible only for something like a quarter of the total volume. The remainder is made up of plates and supplement illustrations, which represent practically every branch of modern process work, particularly in three-colour and two-colour

half-tone, and represent all classes of work from the avowedly commercial catalogue illustration to the facsimile reproduction of paintings and drawings. Not only these, but the special needs of the newspaper and magazine printer in the way of illustrations are considered, and we have examples of the results obtainable by the use of the coarse half-tone, which is printable on a rotary machine, as also of the half-tone illustration telegraphed by the Korn method. It is not too much to say that no such vivid conception of the facilities of modern illustration methods can be obtained in any other way, and there can be no doubt that the art editor and publisher of books or magazines find just as much interest in the "Process Year Book" as do the members of the trades which are here represented. Mr. Gamble, with true catholicity, draws his examples from all parts of the globe, and it is interesting to compare the work in three-colour by process houses in this country with that by those in America, Sweden, Spain, Portugal, Holland, New Zealand, Belgium, Italy, and Switzerland. In fact, the only productive country, curiously enough, which appears to lack representation is Germany, whilst Austria is represented only by Messrs. Angerer and Göschl, of Vienna.

**PHOTOGRAPHIC RECIPES AND FORMULÆ.**—A useful compendium of formulæ has been issued from the office of "Focus," price 6d. The work of compilation has been done by "Richard Penlake," by whom a good deal of frequently needed information has been brought into a small space. The sections into which the book is divided are: Developers for plate and films; clearing, fixing, and hardening baths; intensifiers and reducers; printing-out paper (P.O.P.); bromide and gaslight papers; lantern slides; platinotype process; carbon process; varnishes, mountants, mediums, and backings; miscellaneous.

#### FORTHCOMING EXHIBITIONS.

December 11 to 14.—Hove Camera Club. Sec., Stanley Read, 12, Old Steine, Brighton.

December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Entries close December 18. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

January 14 to 28.—Glasgow Southern Photographic Association. Entries close January 4. Sec., W. Bryce, 29, Somerville Drive, Mount Florida, Glasgow.

January 30 to February 1.—Nelson Photographic Society. Entries close January 20. Sec., Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

February 23 to March 2.—Birmingham Photographic Society. Entries close March 2. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.

March 7 to 14.—Leicester and Leicestershire Photographic Society. Sec., Lewis Ough, F.C.S., Fernleigh, St. James's Road, Leicester.

March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.

March 9 to 12.—Worthing Camera Club. Entries close February 29. Sec., Edmund F. H. Crouch, 11, South Street, Worthing.

March 12 to 14.—Shropshire Camera Club. Entries close March 2. Sec., W. D. Haydon, The Schools, Shrewsbury.

March 16 to 19.—Cripplegate Photographic Society. Sec., J. G. Denyer, 15, Ostade Road, Brixton Hill, S.W.

The "Camera House Journal" for the current month contains reasonable information regarding lantern outfits, slides, cinematographs, Christmas cards and mounts, etc., together with a description of an accessory specially adapted for photographing flowers. Particulars of Messrs. Butcher's stock-taking clearance sale are also given, some of the items in which appear to be very good value for money.

## New Apparatus, &c.

The "Dega" Electro-flash. Sold by Chas. Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E.C.

This portable apparatus supplies a convenient means of employing the "Agfa" flash-powder, a composition which, as our readers must know, is very rapid in combustion and remarkably free from smoke or other after-products of the flash. There is a sharp distinction between the light grey mist which floats in the air or is rapidly swept away in a draught after the combustion of the Agfa powder and the dense body of smoke which is the after-product of less perfectly compounded mixtures. Moreover, the colour is agreeable, almost that of gaslight, and does not on this account startle the sitter, as

would a bluish light of similar great brilliancy. It is true that exposure is over before a nervous sitter could shrink from the light, but as two or three successive exposures may be made the agreeable colour of the light is a legitimate matter for consideration in the choice of a flash.

The apparatus in which the flash-powder is to be used consists of a tray measuring about 8 x 3 in., supported on an oak case, which stands about 9 inches in height. The case contains a dry battery sufficient to supply ignitions for an estimated season's work with the apparatus. The ignition is done with a fuse-wire, about 2 inches in length, which is zigzagged across a pair of brass catch plates. On the circuit being completed by pressure on a button, like that of an electric bell, flash powder spread over these terminals is fired, practically instantaneously.

The convenience of such a device is apparent. The apparatus can be placed in the best position—it is usually well to elevate it considerably—and the flash made at the most propitious moment without rendering the sitters uneasy by adjustments of the apparatus. The charges of powder necessary for different classes of work are given as follows:—

For portraits (1 or 2 persons) .....	4 grains.
„ small groups (6 or 8 persons) .....	15 grains.
„ medium groups (say 20 persons) .....	30 to 45 grains.
„ large groups .....	60 to 90 grains

Some use of the lamp has shown us its reliable character and the certainty of its action. It should certainly be of value to the photographer of "at home" portraits, to whom its convenient size and shape will commend it. Equally the serious architectural photographer will find in it a means of calling flashlight to his aid and of doing so without arousing fears in the minds of vergers and other custodians that his presence is a menace to the building. The price of the "Electro-flash," complete with 100 pieces of fuse wire, batteries, and soft flexible wire, is £1 ls.

"Hyvo," the journal of the Wimbledon Camera Club, reaches us from the secretary of this enterprising society, and is found to include several features of interest, not omitting advertisements. The issue is marked "Xmas Number," the excuse perhaps for its largely frivolous contents; or is this the habit of the gay dogs of Wimbledon, Surrey?

## New Materials.

"OKRO" TONING SOLUTION.—Messrs. Rae Bros., 134, St. Vincent Street, Glasgow, send us a sample of a concentrated toning bath which is deserving of mention, if only for its lack of reducing action on the prints. Using it to tone some score of P.O.P. prints, we could see not the slightest loss in intensity: a print may be made of precisely the depth required, and will not lose anything in the toning process. In other respects the "Okro" solution appears to be a preparation which can be advised. It is diluted with 50 times its own volume of water to form the toning bath, which latter is ready as soon as mixed. The tone given is a blue-black when toning is pushed to the extreme, but the bath gives some very pleasing and warmer intermediate tones. The toning bath has no evident softening action on the gelatine, another good point in its favour.

### CATALOGUES AND TRADE NOTICES.

ZEISS LENSES, ETC.—A new English list of the photographic lenses made at the Zeiss Works, Jena, has been issued by the London house of the Carl Zeiss Endowment, 29, Margaret Street, London, W. It is a handsome volume of over 100 pages, 11 x 7 inches, containing a frontispiece in three-colour half-tone of a studio portrait. The latter serves as a double example of the Zeiss lenses, the original negatives of these and those for the half-tone blocks having been made with Zeiss objectives. The list clearly and fully details the mounting of single and casket lenses adopted by the Zeiss works, the system of marking the working apertures, and particulars of shutters approved by the Zeiss scientific staff. In addition, the list gives prices and drawings of mirrors and prisms, light-filter glass cells and other apparatus issued with the Zeiss hall-mark of workmanship. The list will be sent on application to 29, Margaret Street.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, DECEMBER 13.

Salisbury Camera Club. "Rotary Carbohydrate Paper."  
Sutton Photographic Club. "Touraine and its Chateaux." J. W. Burmester.  
Aberdeen Photographic Association. Scottish Federation Portfolio.

#### MONDAY, DECEMBER 16.

Stafford Photographic Society. Photography 1907 Prize Slides.  
Cattford and Forest Hill Photographic Society. Lantern Slide Competition.  
Criticism. E. R. Bull.  
Scarborough and District Photographic Society. Members' Night. Lantern Slides, Prints, &c.  
Bradford Photographic Society. "An Evening with Pictures." W. Bagshaw.  
Cleveland Camera Club. "Tabloids and their Use." Burroughs, Wellcome, & Co.  
South London Photographic Society. "Excursion Slides and Print Competitions."  
Bowes Park and District Photographic Society. "Rotary Carbohydrate Paper."

#### TUESDAY, DECEMBER 17.

Royal Photographic Society. "Plates Sensitized with Dicyanin, and the Photography of the Infra-Red." C. E. Kenneth Mees and S. H. Wratten.  
Wimbledon and District Camera Club. Members' Evening.  
Birmingham Photographic Society. "Some Hints on the Preparation of Lantern Slides and Diagrams for Lecture Purposes." Dancer Whitlites.  
Sheffield Photographic Society. "My Room to Rome." Rev. J. A. Alderson.  
Keighley and District Photographic Association. "Ozobrome: What Can be Done with it?" W. H. Womersley.  
Blairgowrie and District Photographic Association. "Manuscript Magazine." L. Falconer, jun.  
Worthing Camera Club. "Dive into Belgium." R.P.S. Affiliation Lecture.  
Epsom and District Literary and Scientific Society. "Autochrome Colour Plate." T. Bucknill.  
Leeds Photographic Society. "Theory and Practice of Time Development." W. F. Slater.  
Padiham Photographic Society. "Photographic Chemicals." Burroughs, Wellcome, & Co.  
Heaton and District Camera Club. "Photographic Chemicals." Burroughs, Wellcome, & Co.  
Hackney Photographic Society. "Rotary Carbohydrate Paper."

#### WEDNESDAY, DECEMBER 18.

Mill Camera Club. "Lantern Slide Making." W. Mansfield and W. Swindon.  
Tunbridge Wells Amateur Photographic Association. "Some Illuminated Manuscript Books." George Reid.  
Leeds Camera Club. "In the Haunts of Sea Birds with a Camera." Riley Fortune, F.Z.S.  
Everton Camera Club. Annual Meeting.  
South Suburban Photographic Society. "Palestine as I Saw It." P. R. Salmon, F.R.P.S.

North Middlesex Photographic Society. "Flower Photography." E. Seymour.  
Borough Polytechnic Photographic Society. Lantern Slide Competition.  
Coventry Photographic Club. Judging No. 3 Summer Competition.  
Bristol Photographic Club. "The Port of Old Bristol." J. C. Pearce.  
West Surrey Photographic Society. "Rotary Carbohydrate Paper."  
Birmingham Photographic Society. "Bromide Enlargements." E. D. Taylor.

#### THURSDAY, DECEMBER 19.

Handsworth Photographic Society. Photography 1907 Prize Slides.  
Rodley, Farsley and Calverley District Photographic Society. "Enlarging." John Wood.  
Hull Photographic Society. "Scenes and Incidents on the Yorkshire Coast." Wm. Holmes.  
Richmond Camera Club. "My Fall from Grace." C. H. Davis.  
North London Photographic Society. "Exhibition Afterthoughts."  
Midlothian Photographic Association. "The Chemistry of Developers." Dr. Drinkwater.  
"One Man Show." Jas. Patrick.  
Thornton Heath Photographic Society. "Photographic Chemicals." Burroughs, Wellcome, & Co.  
London and Provincial Photographic Association. "Rotary Carbohydrate Paper."

### ROYAL PHOTOGRAPHIC SOCIETY.

MILKING held Tuesday, December 10, Mr. T. Freshwater in the chair. A paper on "Agar-Agar in Emulsion Making, and a Sepia Paper," by W. F. Cooper, B.A. and W. H. Nuttall, F.I.C., was read by Mr. Cooper.

The authors first reviewed the literature of agar, the first references to which occurred about 1856. In 1880 Morin described the chief properties of agar, and gave its setting-point at about 90 deg. C., as compared with gelatine 60 deg. C. Later researches about 1903 had dealt with the retardation of the setting of agar by certain salts; the rate of setting of agar solutions was affected by chemicals, although no permanent change in the agar itself could be detected.

As a vehicle for the sensitive silver salts in emulsions, agar presented several difficulties: first, the opalescence of its solution, the alterations in the viscosity of the solution, the difficulty of dissolving the agar, and its reducing action on gold chloride. In dissolving agar it was necessary to heat the water to 100 deg. C., and if the solution was cooled suddenly the substance would precipitate and the solution would have to be reheated to 100 deg. C. These disabilities of agar had come before the authors in working out a photographic paper employing agar in conjunction with Mr. Gillard, and therefore they had examined as fully as they were able the properties and reactions of agar.

Agar, unlike gelatine, contained no nitrogen, and therefore belonged to one of the more complex carbohydrate groups, either to the celluloses, starches, or gums. As nitric acid converted it into mucic acid, it probably was a gum, and was classed as such by some chemists. Agar swelled in hot water, and could be washed with cold water, but the operation had to be done quickly, or the agar was liable to discolour.

As purchased, agar contained specks, apparently of cellulose, which had to be removed by filtration. This operation being attended with a good deal of difficulty, it had been found best to make a 1 per cent. solution of the agar and filter it hot through two filter papers on a disc funnel the papers on which could be quickly changed as soon as the solution commenced to run slowly. The filtrate was opalescent, but free from granules. It set at a temperature of 35 C. A lower setting temperature of 32 had been obtained by the use of hydrogen peroxide, but the agar was spoiled in the process. A 1-500 solution of agar set to a jelly. Unlike gelatine, agar on splitting up when the solution was boiled did not form ammonia products, such as glyccoll, and therefore as a vehicle for sensitive salts was probably more satisfactory on account of its greater immunity from fogging action. If heated with water under pressure agar decomposed, and this process, which it was thought might be a convenient means of making solutions, was found useless. Three per cent. solutions of agar were found to be very thick, too viscous for practical work. A solution of agar of the same viscosity as gelatine contained one-eighth the weight of the gelatine.

One advantage of agar as a silver vehicle was the thinness of the film which could be coated. The authors instanced a case in which a plate had been intensified three times and dried in five minutes, washing quickly between each operation. The thinness of the film employed enabled hypo and other salts to be washed out very quickly. Picric acid gave a precipitate with gelatine, but not with agar, and was one of the best tests for distinguishing

between the two. Mercuric chloride behaved similarly. Alcohol precipitated agar as it did gelatine, but it was found a stronger solution takes more alcohol without precipitation than does a weaker one; the ash in the agar was increased by precipitation. The setting powers of agar were destroyed by acids and alkalies, although the solid substance might be soaked in acid without harm. Alkalies made agar more sticky and gummy, particularly if borax was present.

The authors had found that, compared with gelatine, agar absorbed one-thirtieth the quantity of iodine for equal degree of viscosity. Silver nitrate gave no precipitate or discoloration with agar unless the substance was of considerable impurity; in this case citric acid and hydrogen peroxide prevented the discoloration. Agar was unaffected by alum or formalin.

The authors gave particulars of measurements of the viscosity of agar when treated with various substances. It was found that acetic and tartaric acids quickly reduced viscosity almost to that of water, citric acid acted slowly and did not reduce viscosity to lower than 80 per cent. Silver nitrate reduced it to about 70 per cent. In the emulsion suggested by Mr. Gillard, Rochelle salt and tartaric acid were used, and were the cause of the reduction in viscosity which led to granulation of the prints. Citric acid would obviate this defect, and gold chloride and citric acid might be used together with agar for self-toning emulsion.

Passing to the use of agar for a direct sepia bromide paper, the authors said that sodium phosphate was used by Mr. Gillard in conjunction with a developer consisting of hydroquinone, sodium sulphite and water only. The drawback to the use of ordinary phosphate was that, in conjunction with nitric acid, silver nitrate was liberated, causing great reduction in the viscosity of the agar, and hence granulation of the prints. Tribasic phosphate gave a better emulsion, but the authors finally adopted the use of the ordinary sodium hydrogen phosphate, and added soda at a later stage of the process. By adjusting proportions of potassium bromide and phosphate in the emulsion the colour of the sepia print could be modified to a given colour. The authors described and showed photographs of the experimental drying apparatus which they used for agar paper, and which allowed of the coated roll being rapidly dried at a temperature of about 85 deg. C. (186 deg. F.).

In the subsequent discussion Dr. Mees referred to Schroeder's results in examining alterations in the viscosity of gelatine which were obtained with comparatively weak solutions. He thought if Mr. Cooper measured viscosities of agar in one-tenth or one-fifth per cent. solution he might obtain more concordant results. On the proposition of the Chairman, seconded by Mr. E. C. Morgan, the thanks of the meeting were accorded to Messrs. Cooper and Nuttall. Mr. Morgan, as a manufacturer of agar paper, said that the researches of the authors would be of the greatest possible value, and he could speak for himself when he said that he would have been very glad of such information at the time he commenced to employ agar on a manufacturing scale.

**EDINBURGH PHOTOGRAPHIC SOCIETY.**—At the usual monthly meeting of this society, held in the rooms, 38, Castle Street, Mr. A. H. Baird, F.R.P.S., who presided, referred sympathetically to the death of the hon. treasurer, Mr. John Stewart, who had given faithful and efficient service to the society. It was intimated that Mr. J. B. Peden had been appointed interim hon. treasurer. Mr. John Banks, a well-known Edinburgh professional photographer, read a paper on "Photographing Children." He dealt in a humorous and interesting way with the incidents associated with child photography, and said he considered it one of the most important and difficult parts of the work of a professional photographer. His bright paper was greatly enjoyed, as were also the fine lantern views of children which illustrated it. Several of the amateur members gave an account of their experiences in child photography, which seemed generally to have been of an unhappy kind. Mr. James M. Kerr followed with a paper on "A Method of Testing the Speed of Shutters" by photographing a falling ball. The plan seemed to commend itself to some of the members who afterwards spoke, though others seemed doubtful of its accuracy. Both gentlemen were cordially thanked for their papers. The presentation print for the session (which is given to every member) was distributed at this meeting. The print for this year is a specially fine one, and is entitled "A Bit of Old Edin-

burgh, 1847." It is from a negative in the possession of the society by the late Mr. D. O. Hill, R.S.A., who was a pioneer of artistic photography, and whose work is greatly prized by collectors. This characteristic example shows in the background the famous Calton Hill, and in the foreground an historic old church, which has since been cleared away. The print is rich and soft, a suitable sky has been introduced, and the mounting is in excellent taste.

**SHANGHAI PHOTOGRAPHIC SOCIETY.**—The principal business at the annual meeting of the Shanghai Photographic Society, which was held in the Union Church rooms on October 24, was a lecture and demonstration by one of Messrs. Pathé's representatives upon the taking and preparing of cinematograph pictures. After describing the process fully, the lecturer was called upon to answer questions upon the making of the more wonderful of the pictures, and at the conclusion he was cordially thanked, on the motion of Mr. Mencarini.

**ROTHERHAM PHOTOGRAPHIC SOCIETY.**—An audience of over 300 gathered in the Rotherham Town Hall Assembly Room last week, on the occasion of a lecture by Rev. Bernard Butler, on the subject "Birds in the Garden: A Study of Their Habits Made with a Camera." Mr. C. H. Moss, J.P., the new president of the society, occupied the chair. Not the least interesting part of the proceedings was the delightful way in which the lecturer told his story, presenting many new facts of special import to the naturalist and the photographer. He had first been an observer, and, finding that certain classes of birds were of a friendly disposition when a little extra attention was bestowed, he brought his camera to bear on their movements. He was able to impart much useful information on (1) nesting habits and care of the young; (2) individuality of character; (3) mishaps to garden birds; (4) the initial flight of small birds; and (5) birds in combat. The lecture was illustrated by eighty photographic lantern slides of robins, chaffinches, hedge sparrows, song thrushes, missel thrushes, starlings, blue tits, and ox-eye tits. Cordial thanks were accorded at the close.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—Meeting held December 4, Prof. Armstrong in the chair. Mr. G. Roche Lynch gave a most interesting lecture on "Photo-micrography."

## Commercial & Legal Intelligence.

**IMPUDENT THEFT FROM WELLINGTON STREET.**—At Swansed, last week, James Bannerman, photographer's agent, was charged with obtaining 3s. by means of false pretences from Elizabeth Connor, Wellington Street, Swansea—not Strand, W.C. Complainant said she paid defendant 1s. due to Messrs. Taylor, whom he said he represented. She left defendant alone for a few moments, and afterwards missed 2s. from the mantelpiece. Detective Lewis arrested defendant on Monday in Orange Street. "I don't know anything about it; it must be a mistake," he replied. "On the way to the station defendant said he had been at the house and asked was Mrs. Connor drunk? On getting a reply in the negative, he said, 'I suppose, then, it must be revenge.' When charged, he replied, 'Is that it? I never did it.' Defendant said he sold complainant a portrait on condition that half was paid before she received it. That had not been done. He denied having taken the money. He was sentenced to fourteen days' hard labour.

### NEW COMPANY.

**DIRECT PHOTO-ENGRAVING COMPANY, LIMITED.**—Registered November 23. Capital £5,000, in £1 shares. Objects: To carry on the business of photo-engravers, etchers, lithographers, printers, designers, draughtsmen, etc. No initial public issue.

**"PUSHANE" £150 PRIZE COMPETITION.**—Messrs. Fuerst Bros. notify us that they have extended the period of the above until further notice till the end of June, 1908.

**CHRISTMAS HOLIDAYS.**—Messrs. Raines and Co., of Ealing, advise us that their works will be closed from the evening of Tuesday, December 24, reopening on Monday, December 30.

## News and Notes.

**PERCENTAGE SOLUTIONS.**—A sidelight on the awful muddle of our British weights and measures is shown by a letter to the "Pharmaceutical Journal" of last Friday. The writer (Mr. Chas. Flint) states:—In actual practice the percentage formula in our excellent "Codex" may, unless a little thought is used, be productive of small but not unimportant errors; the fault lying not in the formulae as given, but in the non-interchangeability of our English weights and measures. If one were always working in ounces the liability to mistake would not occur, because the avoirdupois ounce of 437.5 grains stands in direct relation to the fluid ounce of 437.5 grain-measures (or 480 minims). But if working, say, in grains or drachms, more care is needed in the final adjustment of volume. Two examples will make this clear:—(1) In making liq. atropinae sulph., and starting with one grain of the salt, the finished product should be 100 grain-measures or 110 minims (not 100 minims). (2) In preparing liq. ferri iodid. fort., if one works in drachms, making the final product 100 drachms, the quantities of iron and iodine will be 20 x 55 grains and 66.5 x 55 grains respectively (not 20 drachms and 66.5 drachms). Of course, to always work in ounces and decimal parts of ounces would obviate all difficulty and chance of error, and for this purpose the per cent. table at end of book is extremely useful, even if only to check one's figures.

**"PHOTOGRAMS"**—Messrs. Dawbarn and Ward, who, under the title of "Photograms of the Year," bring the year's crop of pictorial photography to our firesides, have to pay sometimes for their persistent advocacy of "photogram" as a substitute for the universal "photograph." In the "Westminster Gazette" a few evenings ago, the headline, "Photogravures of the Year," startled us into the supposition that another annual was to gather the pictorial fruits of the camera. But there is no cause for alarm; it was our old friend "Photograms," reviewed, no doubt, by some scribe more gifted in the mind than with the pen. And the compositor—well, we can imagine him making the best of "photograms."

**COLOUR PHOTOGRAPHY AT THE POLYTECHNIC.**—An exhibition of examples of colour photography will be held at the Polytechnic, Regent Street, during the Christmas holidays, commencing December 26, 1907. Silver and bronze medals will be awarded as follows:—A.—Portraiture by the Autochrome process (silver and bronze medals). B.—Other subjects by Autochrome process (silver and bronze medals). C.—Colour prints by any purely photographic process (silver and bronze medals). No entry fees, and the exhibition will be open free to the public. The exhibits will be judged by Mr. George E. Brown, F.I.C., Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY. The following conditions must be complied with:—

Entry forms properly filled up and signed must be posted to reach Mr. C. H. Hewitt, 309, Regent Street, London, W., not later than Friday, December 20, 1907.

Exhibits, which must be individually labelled with the exhibitor's name and address, should reach the Polytechnic, if possible, not later than Monday, December 23, 1907, the latest date for receiving same being December 28. They should be addressed as above and sent carriage paid.

Autochromes should be varnished and protected by cover glasses, and paper prints must be mounted and framed.

Every care will be taken of exhibits, and they will be carefully packed for return at the close of the exhibition, but no liability for accidental damage can be accepted. Exhibits will be insured against fire at value appraised by the Polytechnic.

Owing to the limited space available for the display of the exhibits, acceptance of all pictures sent cannot be guaranteed, but all pictures will pass before the judge.

**AN AUTOCHROME NATURE LECTURE.**—Mr. F. Martin Duncan, whose recent lecture on "The Romance of Insect Life" we referred to on its delivery at the Blenheim Club, has now made arrangements to demonstrate his pioneer work in the application of colour-photography to the record of animal mimicry before London and provincial audiences. Mr. Duncan's monochrome photographs have in the past provided a feast of entertaining information; in colour, however, the

nature subjects which Mr. Duncan has made his own gain enormously in interest. The new lecture, "The Romance of Insect Life," should be a very popular fixture, and we can give no better counsel to secretaries and amateur entrepreneurs generally than to address Mr. Duncan at 39, Bradley Gardens, Ealing, W., for vacant dates.

**A SHOW OF ARTIFICIAL LIGHTS.**—Interest having been taken late in the use of artificial lighting for the photographic studio, partly no doubt owing to the recent exhibition at the offices of the "B.J.," Messrs. O. Sichel and Co. have with commendable energy taken a step which should be appreciated by those anxious for the opportunity of comparing the various types of lamp. They have installed studio lamps of the open, enclosed-arc, and mercury-vapour type at 52, Regent Street, next to Piccadilly Circus, W., where under the superintendence of Mr. A. Holmquist, who is a qualified electrician, the respective outfits may be tested by anyone who so desires. Messrs. Sichel have placed one of their cameras, fitted with a portrait lens, at disposal for this purpose, and allow photographers to use their own plates, which should be half or quarter-plate in size, for the tests. It is not to be assumed that such a trial is altogether on all fours with one made in a completely fitted studio, but it is nevertheless one which should be of considerable value to any one desirous of accommodating himself with a particular description of artificial light installation. Moreover, on the same visit they can be afforded the opportunity of seeing the actual working of a printing outfit by artificial light. Enquiries as to special requirements should be addressed to Messrs. Sichel at 52, Bunhill Row, E.C., but callers at 52, Regent Street, need no introduction other than their alleged interest in electric light for studio portraiture.

**WEDDING.**—Miss Midwood, daughter of Mr. H. Midwood, photographer, of Ramsay, Isle of Man, was married to Mr. H. Kermode, of Castletown, on Monday last, at Maughold Church. A reception was afterwards held at Albert House, Bally Mount, and was well attended.

**"GRENNA" ENLARGEMENTS.**—We have received from Mr. H. Holden, of 10, London Street, Paddington, W., a specimen of these enlargements, which has the appearance of being a bromide, toned to a rather pleasing shade of green. The method by which these enlargements are produced is not stated, but the effect is very satisfactory, and closely resembles that of carbon. It is claimed that they require much less "finishing" than carbon prints, and that they remain just as permanent as ordinary black bromides.

**THE "HENDERSON" AWARD.**—This award, given by the late A. L. Henderson (and open to the world) is of the value of £5, and is given for the best paper read or published during the year from July to July upon a subject, preferably, of a photochemical nature. The award is vested in the committee of the London and Provincial Photographic Association (of which Mr. Henderson was the founder). This year the award falls to Dr. C. E. Kenneth Mees for a paper upon "The Rendering of Colour and Colour Contrasts."

**PHOTOGRAPHER FOR L.C.C.**—The London County Council, at its meeting on Tuesday, decided to appoint an expert photographer and lantern-slide maker. The matter arose on a suggestion by the Education Committee that the 450 lanterns in day and evening schools possessed by the Council should be fully utilised, as lantern pictures are a valuable aid to teaching. The Establishment Committee, in a report on the subject, mentioned that at present the general photographic work of the Council is done by Avery and Co. by contract. The accommodation in the L.C.C. chemical department would allow of the work being done there without inconvenience. The Council has at present 27,000 slides, and the work of preparing new ones and supervising the collection, it is thought, will occupy one assistant almost the whole of his time. The Council will determine their contract with Avery and Co. and try the experiment for one year. The salary attached to the post is £200 per annum, and provision is made for the appointment of two assistants at a rate of pay not exceeding £2 a week each. The Finance Committee remark on the possibility of there being a greater demand for photographs under the new system, and ask the Establishment Committee to see that due economy is exercised by other committees in ordering photographic work.

## Correspondence.

\**Correspondents should never write on both sides of the paper.*

*No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

### PORTRAITURE BY THE MERCURY-VAPOUR LAMP.

To the Editors.

Gentlemen,—In your issue of December 6 a letter appears condemning my article, which appeared in your issue of November 22. Mr. Girdlestone says that I “depreciate other systems.” I do, so far as I can compare them with the mercury-vapour lamp. He then goes on to say that “nearly all my statements in the second paragraph can be flatly contradicted.” We are further on referred to Mr. Hewitt’s article of November 8. I will, first of all, deal with the “statements” which Mr. Girdlestone can “flatly contradict.” Regarding “the uncertainty of the electric arc lamp and the difficulty of starting the lamps” (I quote this from my article), I can give an instance which happened only a fortnight ago. I was paying a visit to a well-known provincial firm of photographers, and their manager was anxious to show to me their new installation of eight up-to-date arc lamps. The lamps could not be started when the manager wished, and, finally, a telephone message had to be sent to a firm of electricians in order to have things put right. I might mention that this firm had used arc lamps for at least seven or eight years. I think this would prove to any beholder that the “uncertainty and difficulty in starting” was present. Then as to the next point—“heat,” I quote from Mr. C. H. Hewitt’s article, in your issue of March 2, 1906. Mr. Hewitt says: “The heat given by these enclosed lamps is considerable, and in carbon printing it is very necessary to keep the frames at a sufficient distance, so as to avoid heating the carbon tissue.” Can Mr. Girdlestone now contradict my “statement” that there is heat connected with the arc lamp? I repeat, that none of these faults appear in using the mercury-vapour lamp. Mr. Girdlestone takes exception to the fact that, “although for ordinary purposes the plates have been of the same speed, when used with the mercury-vapour lamp each plate has required a different exposure.” This fact I adhere to, in spite of Mr. Girdlestone’s sarcastic allusion to it as being an “advantage.” If Mr. Girdlestone will take the trouble to read my article again he will find that I was simply giving the results of certain experiments I had made with different brands of plates, a hint which was well received in various quarters. The last point quoted by Mr. Girdlestone is in connection with exposure—“expose for six seconds,” and “in no case exceeding nine or ten seconds.” Because I have written these words I am supposed to have disposed of any claim the mercury-vapour lamp may have for portraiture work (vide Mr. Girdlestone). Referring to the exposure of nine or ten seconds, this was found to be the longest exposure necessary when using an “ortho.” plate, a stop which I did not recommend. The exposure of six seconds was given with a Royal Standard plate, “under the conditions set forward in my article.” The conditions mentioned are briefly as follows:—The sitter was placed about six feet from the lamps. Lamps were covered with nainsook, a second screen placed nearer to the sitter, and the red blind drawn upwards until the light was concentrated on the face. As I mentioned before, the exposure was six seconds. I now quote from Mr. Hewitt’s article of March 2, 1906. “The portraits of children show what can be done in the way of cutting down exposures, while the half-length portrait, in which the light has been controlled so as to secure some concentration of light and shade, was given an exposure of from two to three seconds under the conditions stated.” The said conditions are pretty much the same as those under which I work with the mercury lamp—viz., eight feet from lamp, stop  $f/6$ , and special rapid plate. Mr. Girdlestone will scarcely relish the fact that, with a No. 114 Westminster lamp, Mr. Hewitt gave three seconds’ exposure, whilst with only two mercury-vapour tubes, an

exposure of six seconds was sufficient. Dealing further with the question of efficiency, Mr. Hewitt is quoted as saying that, with the No. 114 lamp, an exposure of a quarter of a second is sufficient for ordinary work. If Mr. Girdlestone cares to take the journey north I will demonstrate to him that I can get a correctly exposed negative with a second’s exposure, and that with only two tubes. Since Mr. Girdlestone has mentioned exposure he will no doubt be pleased to hear that, whereas a Westminster No. 114 lamp, consuming seven units per hour, gives an exposure of a quarter of a second, six mercury tubes, consuming a little under three units per hour, will allow of an exposure of one-third of a second, or, to take it further, a Westminster lamp, running at a cost of 2s. per hour, is very little better than a Cooper-Hewitt skylight of six tubes, running at a cost of about 10d. per hour. But Mr. Girdlestone must not presume that the efficiency of the vapour lamp ends here. Let him refer to von Hübl’s paper on the arc lamp (“B.J.” Nov. 1, 1907), and he will see that, in printing, the arc lamp is very difficult to adapt to printing large negatives. I quote as follows: “Practically when printing a negative, 20in. x 20in. square, at a distance of 20in. from the light source, the margins receive 75 per cent., and the extreme edges only 55 per cent. of the light that falls upon the middle.” I would like to point out that, with the negative placed at 20 inches from the source of light, a negative at least 40in. x 56in. can be printed from with the five mercury tubes mentioned. Touching again on portraiture, I would like to draw Mr. Girdlestone’s attention to the fact that, even when the mercury tubes are uncovered, the light is perfectly diffused, and is evenly distributed over the whole area of the skylight, a state of things which is non-existent in the case of the arc lamp (see Hübl’s paper, “B.J.” Nov. 1, p. 826, second column). I have endeavoured to justify my “statements,” as made in my article of November 22, and have omitted to deal with the charge of incompetence made in the first paragraph of Mr. Girdlestone’s letter. It may be well to mention that I cannot enter into any further discussion on the matter.—I am, yours faithfully, GEO. R. HENDERSON.

Hebburn-on-Tyne.

P.S.—It may astonish Mr. Girdlestone to read the following, which I quote from a letter received from a photographer at Bexhill-on-Sea: “I have visited the Artificial Light Exhibition \*\*\*\*\* \*\* arc lamps, etc. \*\*\*\*\* Should I decide to adopt artificial lighting I shall use your system, as I consider it is nearer daylight than any other.—Yours sincerely, “M——.”

### STAND DEVELOPMENT.

To the Editors.

Gentlemen,—The article by Mr. Mackie last week dealing with the leaflet recently issued by us, represents our position in issuing that article very fairly, but we may perhaps make a little clearer the reason for the differences on some points between Mr. Mackie and ourselves.

Owing to the rather special nature of the plates, screens, etc., which we manufacture, we receive a very large number of inquiries, frequently of a technical nature. When inquiries reach us which we have not the knowledge to answer, we institute an investigation into the question if the subject appears to be of general interest. We publish the result of those investigations in three different ways: (1) As booklets of a more or less advertising character, which are given away and distributed as such; (2) as leaflets giving our information on the special subject under discussion, and written mainly in order that a printed leaflet may be sent to save the writing of special letters; and (3) if the subject is of purely general interest, the investigation is published, not by ourselves, but as a paper before some society, or in a journal, and under the names of those who did the work.

The leaflet on stand development belongs to the second of these classes; it is practically an answer to the following questions which we have frequently received:—“I am using your colour-sensitive plates, and you give the time of development with your developers. I am used to stand development; can you give me a formula and a time for a diluted developer which shall take from half to one hour for development?”

This question we could not answer until we had made the

measurements described in the leaflet on stand development, and consequently we assumed at the beginning of that leaflet that for a developer to be satisfactory we must be able to tell users of our plates how long to develop with it. The necessity for this arises from the special colour-sensitive nature of some of our plates, which renders time development almost imperative. This, then, is the reason for the point of view to which Mr. Mackie refers.

We may take this opportunity of referring to one or two other points which have arisen since the publication of that leaflet. We stated that we did not recommend rodinol for stand development. We pointed out that the reason for this was simply that it was not easy to give a time of development for diluted rodinol solution. This objection, of course, only applies when using strongly colour-sensitive plates which cannot be inspected, and dilute rodinol is a quite satisfactory developer for stand development when judging density by inspection, just as we have always found a more concentrated solution of rodinol generally satisfactory, and recommend it for time development with our colour-sensitive plates.

Then, with regard to Mr. Mackie's point as to the causes of fog, Mr. Mackie remarks that some of our suggested causes of fog are far-fetched. We did not say that the causes we give would produce fog, we said that they may "unite to attack plates." This has nothing to do with a particular plate. Fumes of burnt gas will tend to attack any plate during development, just as Mr. Mackie's example is true of all plates. Pyro-ammonia will always tend to produce green fog, though with satisfactory plates the green fog will not be noticeable.

If, however, a plate is liable to produce green fog, pyro-ammonia will show it more readily than other developers, and that statement seems to us to be true of plates generally. We do not know of any differences between behaviour of different plates with regard to diluted developers, but if Mr. Mackie can suggest any further experiments which would be of general use, we shall be pleased to take his suggestion and continue measurements upon development with dilute developers.—We remain, Sir, yours faithfully,

Croydon.

WRATTEN AND WAINWRIGHT, LTD.

To the Editors.

Gentlemen,—Messrs. Wratten and Wainwright's leaflet on "Stand Development" was obviously addressed to users of their own plates, and, such being the case, they may legitimately urge that its contents were of a semi-private nature, having no general application. The publication of the leaflet in these pages, however, may cause many to regard it as an "Ex Cathedra" statement applying universally, and in view of such an opinion Mr. Mackie's paper, in your issue of last week, must be sincerely welcomed. It is a matter of common knowledge, referred to not long since by yourselves in these pages, that laboratory experiments do not always chime in with everyday practice, and many of the dogmatic statements emanating from the laboratory regarding development are singularly illustrative of this fact. All crafts at the present day are too much indebted to accurate scientific research to be able to ignore its teachings, and the man who elects to work by empirical methods alone will quickly reach the place reserved for him in the survival of the fittest; but in hard everyday work much laboratory teaching has to be considerably modified in one direction or another. It may be true, from the laboratory point of view, that "stand development" is inadvisable, and the means of introducing errors into one's work, but the fact remains that in everyday practice it is a most convenient method of development, and gives negatives that will stand comparison with any developed by the tray, either "timed" or "rule-of-thumb."

The practical photographer who values the reputation of his work cannot afford to sacrifice technical quality, neither can he afford to ignore any means whereby time and labour may be saved. If the quality of negative by stand development was in any way inferior to tray developed negatives I, for one, would have none of it, and it goes without saying that in the workroom any method that is inconvenient and consumes time and labour must eventually be set aside. On the other hand, it would be absurd to advocate stand development to the exclusion of other methods; to the man with only a few nega-

tives to develop there can be no advantage in making up a bath of thirty or forty ounces just for the sake of using this form of development. But the case is far different with him who is developing most of the day, or who has large batches of plates to develop at a time.

With regard to the evils Messrs. Wratten associate with stand development in their leaflet I am bound to say I have not yet met with any of them. Of course, one must always bear in mind, as Mr. Mackie pointed out in his paper, that Messrs. Wratten are writing with special reference to their own plates, so that when they write of general fog and edge markings occurring with stand-developed plates it must be taken with this reservation. I have developed several brands of commercial plates by "stand" without any trace of fog, marginal or general; but, as Mr. Mackie also points out, there is always the plate, which is the host that has to be reckoned with.

When my paper on "Stand Development" appeared in your pages ("B.J.," July 12, 1903, p. 520), I had letters from several correspondents complaining that their experiences varied considerably from my statements, and mildly suggesting that I was in error. One correspondent complained that with the formula I gave he could not get sufficient density with X's plates, even in half an hour. Curiously enough, a few days after receiving this letter, a user of the same plate complained to me of the length of time it took him to get average density with them, and he used their own developer and tray development.

I believe that at the present time the want of a convenient tank stands very much in the way of the acceptance of stand development. Personally, I want nothing better than the porcelain dipping bath, which is economical of solution, light-tight, and easily kept clean. A tank that requires some thirty ounces of developer to make it available for use is sure to have a deterrent effect, especially when the number of plates to be developed is small, and they are of moderate dimensions. Tank development does not necessarily mean dilute solutions, so that to dilute a standard strength of developer merely to fill a tank too large for the purpose is scarcely a sound proceeding, as extremely dilute solutions, with consequent prolonged development, is not unlikely to cause general fog.

In spite of Mr. Mackie's optimistic views of the future of stand development it is open to question whether photographic workers will make use of it to any great extent, not from any lack of merit in it, but from the fact that the bulk of them can get along very well with the tray. It is the worker who finds himself with continual developing to do who is likely to cast about for some certain and efficient means of saving labour and time. Tank development for negatives at the present time is on all fours with tank development in carbon work. Where a dozen or so only are in consideration the need for a comprehensive method is not particularly felt, but when it is a question of developing some dozens the ease and convenience of the tank method become at once apparent.—I am, Gentlemen, yours faithfully,

G. T. HARRIS.

Sidmouth, Devon.

#### PORTRAITURE BY ARTIFICIAL LIGHT.

To the Editors.

Gentlemen,—At present photographers are greatly interested in artificial lighting. My experience has been simply incandescent gas. The enclosed photograph was taken at night, with five large burners, on special extra-rapid "Royal Standard" plates. The exposure was ten seconds at  $f/6$ . It is one of the best I have done. The retouching on face is slight; the eyes not touched. Please note high-lights. If you, gentlemen, have seen better work with so small amount of light I shall be pleased to hear of such.—Yours faithfully,

92, East Street, Bedford.

A. E. STANLEY.

[The photograph is certainly very well lighted, unmistakably by an artificial source. Our correspondent can scarcely suppose that 10 secs. is a practicable exposure for the average run of sitters. The present example illustrates the way in which the sitter has had to be practically wedged so as not to move, as well as the insufficient diffusion of the illumination.—Eds. "B.J."]

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- J. Thomas, 81, Rhondra Street, Swansea. Photograph of *Bethania Calvinists' Methodist Chapel at Glanamman.*
- C. Spence, Jessmont, Dunbar, Scotland. Photograph, *View of Knock-in-Hair, Dunbar.*
- H. J. A. Turner, 69, Mount Zion, Tunbridge Wells. Photograph of *Short-eared Owl.*
- G. Moss, The Priory Studio, Church Street, Christchurch, Hants. Photograph, *Group of H.T.M. the Emperor of Germany and Suite.*
- W. Hollick, 78, Wellington Street, Woolwich, London. Photograph entitled, *"You Smile, Dolly."*

SOLAR.—We should say yes to both inquiries.

ON-COLOURING.—Please can you inform me how to prepare matt-surface photographs for painting in oils?—H. SYMONDS.

To matt the surface, apply fine pumice powder with a tuft of cotton wool, and, if the surface is found to require it, rub over light drying oil and leave for twenty-four hours.

FLUATE OF SODA.—On page 705 of the "Almanac" for 1904 is described the early printing process called "fluortype." In the formula is mentioned "fluat" of soda. I cannot get it at any of the dealers' or chemists' here. They do not know the chemical. Is "fluat" a misprint, or an old name for some other salt of soda? I should like to try the process, as I have an idea it is really useful.—A. J. SHEFFIELD.

Sodium fluoride, obtainable from any large chemist.

LAMP SCREEN.—Could you inform me the composition of the coating on the glass plate sent herewith? It is a portion of a backing plate for a large transparency used in a hall lamp which has been broken, and which I have been asked to reproduce. It appears to me to be some exceedingly fine substance held in suspension in collodion or something similar. It is just sufficiently opaque to obscure the source of illumination. It has evidently been flowed on to the plate. I believe the transparencies are of American origin.—TRANSPARENT.

We are unable to tell you the exact composition of the coating. It is evidently a spirit varnish, similar to ordinary negative varnish, with a white pigment, such as sulphate of baryta, added. A sheet of thin opal glass will answer the purpose equally as well, and will have a similar appearance in the lamp.

R. RUSSELL.—We cannot. We inserted a paragraph last week asking for the information, and will publish it as soon as we hear.

STUDIO AND BLINDS.—Would you be kind enough to advise me as to building a studio. The length is 32ft., width 18ft. I wish to build on a single slant. How much width and length of glass do you advise, and is 45 degrees the right angle? Also what blinds would you advise? Should be very glad of any advice you can give. Also what height from floor should glass commence?—S.

If you refer to the issues of the "Journal" for August 23 and 30, pp. 655 and 659, you will find all the information you seek. It is more fully given there than is possible in this column.

R. H. (Hereford).—We refer you to page 613 of the "Almanac." We agree with you as to the difficulty of reconciling the various statements.

COLOURED ENLARGEMENT ON OPAL SHOWING SPOTS.—A few years ago I had an enlargement made on opal and painted in water-colours. It has never been framed, but simply kept in a box. Recently some irregular spots almost black in colour have made their appearance, and I shall be glad if you can tell me any method of getting rid of them. Presumably the enlargement would be in bromide, and the appearance of the spots suggests that they are caused by damp acting on the bromide. I may add that the room in which the opal enlargement has been kept has for some time past been damp owing to defective pipes against the outer wall. Assuming the cause to be as suggested (1) Can the spots be removed by immersing the opal in some chemical solution? (2) Would there be any risk to the picture in this procedure? (3) Are the spots likely to spread if every care is taken to keep the opal in a dry place? Your advice will be greatly esteemed.—C. M. ROBERTS.

Without seeing the picture we can express no decided opinion. In all probability, however, the spots are due to mildew in the gelatine through the picture being kept for so long a time in a damp place. (1) If the picture is coloured with water-colour, that, of course, would be injured if it were wetted. (2) Yes, certainly. (3) If there is any mould on the surface it may probably be rubbed off with a piece of dry cotton wool. Then, if the picture be kept perfectly dry, it is unlikely that the spots will spread further.

R. WILLIAMS.—The Platinotype Co. sell silk, etc., sensitized with the platinum solutions; the method of use is that of platinum printing. A somewhat similar fabric bearing bromide emulsion is sold by the Rotary Co., 12, New Union Street, E.C.

INTENSIFIER.—I am using the metol-hydroquinone developer, and sometimes find the negatives would be better for a little intensifying. Will you kindly tell me the best formula to use?—S. J. MOORE.

The process most likely to suit you is the single solution mercuric iodide, as supplied by the Lumière Co., Great Russell Street, W.C.

W. A. O.—Try the preparations given in the Almanac for bromide enlargements, p. 836. Write us further if you do not find this all you want.

R. STEWART (Melbourne).—We thank you for yours of November 6. We regard the subject as one which calls for much more investigation than we can give it before we should deal with it in our columns. We must confess to an "a priori" sense of scepticism, but we are always open to propositions of experiments under best conditions which a photographer could apply himself.

A. H. DEANE.—Wratten and Wainwright, who will advise you on your stating your requirements. Some notes on stage photography without flashlight appear in the Almanac, p. 725.

W. C. TIERNEY.—The Todd-Forst lamp, the Schroeder (Fallowfield), or the Electroflash (Chas. Zimmermann and Co.).

TONING BROMIDES.—Kindly give a formula for toning gaslight or bromide postcards to a dark brown colour. Simple method.—ANXIOUS.

We can only suggest sulphide toning according to the usual formulæ, e.g., that in the "Almanac," p. 825.

DR. STEPHEN G. LONGWORTH.—It is not on the market to our knowledge. We can best refer you to Newton and Co., 1, Fleet Street, E.C., who could doubtless make one.

AUTOCHROME.—(1) Reference "B.J." of December 6, page 93, I am not clear what is a 2 per cent. solution of bisulphite lye. Does it mean a 2 per cent. solution of sodium bisulphite, or a 2 per cent. solution of commercial bisulphite lye, which, according to König (see "B.J.A.," 1908, page 626), is 35 parts of sodium bisulphite to 100 of water, or roughly 1 to 3? (2) Similarly reference, page 921 of "B.J." of December 6, paragraph 4, line 5, I presume 1 c.c. of bisulphite solution means 1 c.c. of commercial bisulphite lye, or 17 minims of a solution composed of water 100 parts, bisulphite of sodium 35 parts?—E. Y. E. N.

(1) A 2 per cent. solution of the commercial lye is evidently intended by M. Gravier, but we see in a later article in his own journal, "Le Moniteur," that he prescribes a 5 per cent. solution of the lye, i.e., 5 ccs. per 100 ccs. of water. We think the

exact strength is not very important; in fact, we have used the method without the bisulphite bath, but no doubt a weak reducing bath is advantageous as a destroyer of the last traces of the permanganate. (2) The reference is certainly to the bisulphite solution obtainable in this country from the Lumière Co., Great Russell Street, W.C.

**AUTOCHROMES.**—1. Can these be used as lantern slides, with or without precautions taken to protect from heat? 2. If the latter, what is the best way? 3. Are there any appliances on the market to mark the two and a half minutes by sound, such as sandglass with bell, etc.—WEEDEE.

1. They can, but the film is liable to crack if it becomes hot. 2. The transparencies should be varnished with a celluloid varnish and a water trough placed between them and the light if the latter gives out much heat. 3. The oil-shops sell a sandglass with bell indicator for a range of three to seven minutes, but we do not know how accurate it is. The Welborne-Piper clock (Butcher and Sons) is an accurate instrument for the same purpose.

**THISTLE.**—Exactly. The "dry" is all sulphite; the crystallised contains half its weight of water.

**TROUBLED.**—We should take no notice. In the first place she has to prove that the photographs were unsatisfactory; in the second to explain why she refused a second sitting. You had better retain the money.

**PYRO DEVELOPER.**—In this week's issue of the "B.J." you print an article on "Preservation of Pyro in Solution" (Lumière), recommending commercial soda bisulphite sol. 1. Is this obtainable in England now? If so, price, etc.? 2. Is this method better or as good as the neutral sulphite pyro you advocated? 3. Kindly give formula in English measures to make up, say, 20 oz. or 80 oz.; nothing is said about the accelerator (B. sol.). 4. I have used your neutral pyro ever since articles and formula appeared in "B.J.," and like it much for several things; but after keeping for some time it seems to alter, i.e., I fancy I get denser negatives with a fresh-made pyro. My method is to make a stock sol. with the sulphite and metabisulph., then from that make the pyro, using an ounce bottle at once (calling it 440 gr.) so as to save the time in weighing out 160 gr.; this makes just three bottles of pyro sol., and No. 3 seems to act differently from No. 1. Exposures principally in studio.—WEEDEE.

1. The commercial sodium bisulphite referred to is, no doubt, the "bisulphite lye" obtainable from Messrs. Lumière's London agents in Great Russell Street. 2. We cannot say, not having tested Messrs. Lumière's formula. 3. In English measures, use 10 minims of bisulphite solution to 20 oz. of 3 per cent. pyro, or 20 minims to 20 oz. of 50 per cent. pyro. 4. You do not say how long your No. 3 solution has been kept, and some change is to be expected in the course of time. We should use the crystalline form of pyro that is easily weighed, and make up less at a time. An absolutely fresh solution is probably more powerful than one that has been kept, but a good deal depends on the quality of sulphite used. The special advantage we claimed for the formula was the keeping quality of the neutral sulphite alone. This enables one to make up fresh pyro solution at any time with the minimum of trouble.

**STAINED NEGATIVE.**—I herewith send you a negative, which, as you will see, is covered with small yellow stains. Could you, through your valuable paper, tell me how to prevent them? The developer used is pyro-soda.—B. Vos.

It is difficult to say with any certainty what the stains are due to, but they look very like irregular patches of pyro stain. They might be due either to the use of developer containing floating particles that required filtering out, or to the use of an acid fixing bath that was not sufficiently acid or too much exhausted to work properly. In either case the remedy is obvious. Possibly, however, imperfect fixing is the cause. From the appearance of the stains, they were produced either during fixing or developing. Pyro stain is sometimes irregular in its effect owing to the causes mentioned, but similar effects may also be produced by careless washing between development and

fixation. If washed at all, the plate should be completely immersed in water, but such washing is not really necessary with pyro soda.

**CARBON TROUBLES.**—In my business I have been working the carbon process since almost the beginning of the year, and everything has gone on satisfactorily. But now a difficulty has cropped up which promises to put a stop to my operations. Since the damp weather has set in I cannot get the tissue to dry in less than ten or twelve hours, and when it is dry it turns out to be insoluble, so that the pictures cannot be developed. Furthermore, the exposed tissue will not hold on to flexible support. I have to dry the tissue in the dark-room, as I have no other place. Can you help me in any way? I have gas in the room, but I am afraid if I leave that burning so as to warm the place that the fumes from it would bring about insolubility.—PUZZLEN.

An ordinary darkroom is not a suitable place wherein to dry tissue, as the atmosphere in it is generally very damp from the sinks and solutions. Unless you can arrange a more suitable place, we should advise you to employ a spirit sensitiser, such as that sold by the Autotype Company. Tissue sensitised with this will dry in from a quarter to half an hour, and will get you out of the difficulty.

**W. R.—Watts'** "Introduction to the Spectroscope," 10s. 6d., Longman's.

**WET PLATE AND OTHERS.**—In our next.

**TONING STAINS.**—Will you kindly explain red stains in enclosed print? I have many similar.—MIRANDIDDIE.

Difficult for us to say, as you do not even tell us the baths you are using. Traces of hypo or a dirty dish for the toning-bath will give rise to such stains.

**EXHIBITING PORTRAIT.**—Last summer I commenced business at the above address, and about a month ago I took the portrait of the best-known lady in the place, and it turned out one of the best I have taken, and she was very pleased with it. I had a 24 x 18 enlargement, finished first-class, made as a specimen. It had only been in the window a day when her husband came in a great rage and ordered it to be immediately removed. This I refused to do, explaining to him that the negative was my property, and I could do as I liked with it. He then threatened me with the law. Will you please tell me if he can do anything?—YOUNG PROFESSIONAL.

Decidedly he can, and if he does you will find yourself landed in heavy law costs. Although the negative is the photographer's, as we have said many times before, he has no right to use it except to the order of the sitter. You sign yourself a "Young Professional," but when you have had more experience in the business you will find it to your interest not to go against the wishes of customers, and certainly not to give them offence. To give offence to customers, particularly in a country place, is a great piece of folly. Common sense should teach photographers that it is exceedingly bad policy, from a business point of view, to exhibit portraits against their customers' wishes, quite apart from the fact that it is illegal to do so.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The annual index to "The British Journal of Photography" will be published with next week's issue, dated December 27, but to be published on Tuesday next.

Practical directions for the working of the albumen process for lantern slides are given on page 955.

The efficiency of water as a hypo eliminator has been emphasised some recent experiments (P. 954.)

Low temperature as a cause of flat oil prints is the subject of an editorial article. (P. 954.)

Mr. A. Lockett communicates some ingenious geometrical methods making telephoto calculations. (P. 956.)

An American writer describes the tremendous differences between number of professional studios which he visited. (P. 958.)

A fairly correct impression of the demands made on a press photographer is given by a recent writer. (P. 962.)

A cellulose emulsion and a phosphate substratum are among the contents of the week. (P. 964.)

A new and durable incandescent mantle is announced. (P. 953.)

M. Belin demonstrated his method of telegraphic transmission of photographs before the French Photographic Society last week. A Danish inventor is reported to have worked out a wireless method of photo-telegraphy. (P. 953.)

Dr. Herman Weisz records the results of experiments on the latent image on plates free from gelatine or other colloid body. (P. 960.)

## EX CATHEDRA.

### The Annual Index to the "B.J."

With next week's issue, dated December 27, but to be published on the Tuesday before Christmas, we shall present the index to the yearly volume of the "British Journal of Photography." The preparation of the index has gone on week by week throughout the year, a course which is necessary to its appearance with the last issue of 1907. In compiling it, our aim has been not only to indicate the references to a given subject, but to distinguish as minutely as possible between the various items. Although we have improved the index in this respect to a considerable extent, we have done so, we are glad to say, without increasing its length. Last year we recollect a contemporary naively priding itself on issuing the largest index of any photographic periodical. If we were content to dispense with the classification of the hundreds of entries which make up the "B.J." index we should spare ourselves not a few hours of labour, but the reader's labour in consulting the index would be doubled or trebled. As it is, we have aimed at an index of the utmost brevity consistent with the maximum of precision. We shall be interested in hearing the views of any readers who may have opinions on what should and should not be indexed and on the way in which an indexer should set to work.

\* \* \*

### Durable Weisbach Mantles.

It is announced in Paris that a French firm have succeeded in solidifying the rare earths used for the Weisbach mantle, by means of the electric furnace; at the same time the oxides retain their radiating properties. The results have been controlled by a well-known physician, M. Berget, and the Société Hella will shortly put its "buissons ardents" on the market. This slightly irreverent name is due to the form of the ordinary burner, the substitute for the mantle being cast in the form of a thicket or bush of filaments, but any desired shape can be formed, so that the process lends itself to effects. Since the new filaments resist shocks, tremors, or draughts to an enormously increased extent, and can be employed with acetylene Bunsen burners, or for heating in the air by the electric current, as in the Nernst lamp, an advance almost as great as that of the original discovery of von Weisbach is perhaps imminent.

\* \* \*

### Photo-Telegraphy.

On December 9, M. Ed. Belin lectured before the French Photographic Society to a numerous and distinguished gathering on his process of telestereography, recently described in the "British Journal." The previous evening he had sent his first photograph over an actual telephone circuit, a test which was repeated on Monday evening. The circuit was from Paris to Lyons, Lyons to Tours, on to Bordeaux, and back by Angoulême to Paris, a distance of over 17,000 kilometres. The transmission of a landscape image:

13 by 18 cms. was accomplished with perfect success, the time taken being slightly over 22 minutes. M. Belin said there was every reason to hope that this would be greatly curtailed; he expects to reduce it to 15 to 10 minutes very shortly. In the course of his lecture he explained how his apparatus could be used for the transmission of images in half-tone. In this case it is simply a question of the cursive stylus in the transmitting apparatus making and breaking contact, the image being reproduced in dots at the other end.

\* \* \*

#### Wireless Photo-Telegraphy.

Meanwhile, it is interesting to note that a Spanish inventor, Señor J. G. Guillen-Garcia, has presented to the Barcelona Academy of Sciences and Arts a description of an apparatus for the transmission by wireless telegraphy of writing, sketches, or photographs. The principle is essentially the same as that of Caselli in 1857, and so far as the transmitter goes, very similar to that of Belin. This latter consists of a cylinder, rotating at a definite rate and traversed by a stylus, which thus follows the image in heliocoidal lines. If the writing or sketch be in insulating ink, the pen by means of a relay makes or breaks a circuit which includes a transformer and apparatus for the production of Hertzian waves. At the receiving station is a similar synchronised cylinder, and the pen records long or short lines according to the incidence of the Hertzian waves on the detector used. For the transmission of photographs the inventor employs, like Belin, a gelatine relief, and converts the variations of relief into current variations as follows: The end of the traversing pen bears a small roulette or wheel contact; this runs over four metallic contacts, insulated from each other, and bounded by two insulators. Each of these contacts is connected by a wire to a disc of ebonite or other insulating material turning at a uniform rate. One of these has a smooth edge, the others have projections or indentations, the same for each disc, but varying from one to another, and all are in contact with a metal cylinder connected to the Hertzian transmitter. According to the reliefs the stylus traverses, electro-magnetic waves of greater or less intensity are transmitted.

#### Elimination of Hypo.

Of late we have on several occasions tested the effect of various hypo eliminators, and, while the results have mostly been unsatisfactory as regards the eliminators tried, the tests have afforded some interesting illustrations of the advantages of washing plates by simple soaking in several changes of water. As a rule, the procedure recommended with the eliminators is to rinse the plate under the tap for from one to two minutes, and to follow this with a soaking in the special eliminating solution for from three to five minutes. The final operation is then generally from three to five minutes' washing under the tap. In our tests we worked according to the instructions supplied and for the times stated, treating one plate with the eliminator and putting a second one through precisely the same treatment, with the exception that we soaked it in plain water instead of the special solution. After the final rinsing the plates were each soaked for ten minutes in equal quantities of distilled water, which was afterwards titrated with centinormal iodine to find the quantity of hypo present. Incidentally we may mention that we generally found equal quantities present in each case, which proved that the eliminator was no more effective than plain water. It was, however, interesting to note the very small quantity of hypo that could be detected. This seldom exceeded

three-quarters of a milligram per quarter-plate after about eleven minutes' treatment with soaking and washing, and this affords pretty clear evidence of the efficacy of simple soakings, alternated with rinsings under the tap. Of course, the effect was not perfect, but it was more near so than we expected, and the results suggested that half a dozen soakings should be quite effective in something less than half an hour. This has, of course, been pointed out before, but somehow the majority of photographers still persist in washing in running water for periods of one or two hours, though such proceedings are obviously wasteful and probably not so perfectly effective as the simpler and quicker method. In the case of prints, running water is decidedly ineffective as compared with soaking.

\* \* \*

#### The Use of Rodinal.

Many photographers avoid the use of rodinal on account of its reputation for the slow attainment of density, while others strongly favour its use, and deny that the disadvantage mentioned is at all serious. We must admit that we have more often been on the side of the former class of photographers. We could easily recognise the convenience of this ever-ready developer, but while we very frequently used it, we only did so when other quicker developers were not at hand. The remarks in reference to rodinal in Messrs. Wratten and Wainwright's paper on stand development reprinted in our issue of November 15 suggested, however, that this developer is probably not often used to the best advantage. It will be remembered they pointed out that air in the water slowed its action very considerably, and that dilution prolonged the time to an extent quite disproportionate to the amount of dilution. Having occasion to make some negatives, and very little time being available, we put this information to a practical test, and, using 1 in 16 rodinal made with distilled water at a temperature of 55 deg. F., obtained all the density we wanted in a time of eight minutes. Previously, using tap water, we failed to obtain anything like sufficient density in ten minutes' development, and had to resort to intensification. Evidently the use of distilled water is of material advantage, and possibly the varying results obtained by different workers is due in a great measure to the use of different varieties of water. Our tap water is excessively hard, and this may have some slowing effect in addition to that due to air contained in the water.

#### THE EFFECT OF TEMPERATURE IN PRODUCING FLAT PRINTS BY THE OIL AND "BROMOIL" PROCESSES.

THE photographic press has recently contained many complaints of unduly flat results that have been obtained by the various oil processes. Apparently the trouble has only been felt very seriously since the advent of the cold weather, therefore it is rather curious that there should appear to be a consensus of opinion to the effect that it is due to heat. It is a plausible theory that in winter we heat our rooms artificially to such an extent that the printing and pigmenting pad dry more quickly than they do in summer weather. In some cases, no doubt, the trouble has been due to quick drying, but it must not be forgotten that a low temperature is also conducive to flatness. Though we have not seen any previous mention of this fact, it is undoubtedly one to be remembered, especially in the case of the "bromoil" process. Contrast in an oil print is only secured when the image is so hardened as to be incapable of retaining water, while the non-image—

sion—retains so much water as to effectually repel the oil pigment. If the image is too flat it means either that the non-image has never been sufficiently absorbent, or that it has partially dried and lost its water. In the first case the result will be flat from the moment pigmentation begins; in the second, contrast will be obtained at first but lost later.

The second of these two effects can easily occur in oil printing by the Rawlins process, because the pigmenting operation is rather a slow one in the hands of most workers, but it is not so likely to happen with bromoil, or with a more rapid process. In the pigmenting of a bromoil print density is very quickly attained, hence contrast is easily preserved, but in the other case density has to be attained more cautiously, and contrast may be lost during the process. Nevertheless, want of contrast has been a serious trouble in the case of "bromoil" during the last month or so, perhaps more so than with ordinary oil prints. It has been found to be due entirely to the low temperature. If the solutions used in preparing the print, or the water baths used for soaking the print, are too cold, the gelatine in the non-image does not swell sufficiently, or become absorbent enough, to hold the water required to repel the pigment, therefore contrast cannot be secured even at the beginning of the pigmenting process. We thus get the other kind of flatness due to low temperature, and it is very probable that this has been the cause of the trouble with many of those who have of late had difficulty in securing contrast. In the case of "bromoil" we need only to keep all solutions and all water used at an average temperature of 65 deg. F. to ensure success. Soaking in tap water below 50 deg. F. is quite useless with this process, and we have little doubt that cold water used for soaking is also conducive to failure in the Rawlins process.

There is no trouble involved in the use of water of proper temperature. In the oil process we can wash out the bichromate and soak the print in several changes of water supplied from a jug just as readily as we can in water drawn from the tap. In the "bromoil" process we can mix the bleaching solution with warm water, and make the hypo bath by diluting a strong stock solution with warm water. The hypo can then be removed quite sufficiently by six changes of water at 65 deg. F. if the print is allowed to soak for about three minutes in each change. The acid solution is naturally warm if freshly mixed, and generally has to be cooled down to 65 deg. F. by allowing it to stand in the dish. We also soak the pad in warm water before pigmenting, as there are reasons for suspecting that the non-image in a print in perfect condition for pigmenting loses a little of its power of repelling the pigment if cooled down by immersion in cold water or by contact with a cold pad.

Our own experience has convinced us that low temperature is a far more serious cause of flat results than too rapid drying of the pad, therefore we should like to impress upon our readers the importance of using only solutions and water of a normal temperature. We perhaps had better also caution them that the remedy must not be overdone. Solutions of 70 deg. F. and over are too warm to be used with safety. A temperature of 65 deg. F. is a good average, but when the "bromoil" process is attempted on very rough papers coated with a soft gelatine emulsion, a temperature of about 60 deg. F. is advisable. In fact, some of these papers require an even lower temperature, as the gelatine readily becomes too soft. We have been informed that one brand of paper works well during this weather when treated with quite cold solutions, though in August last it was quite useless, as the gelatine came away under the brush. This is, however, a very exceptional case, and the papers in most general use work

best when the temperature of the water is kept between the limits of 60 deg. and 65 deg. F.

#### A NEGLECTED METHOD OF MAKING LANTERN SLIDES.

WITH the lantern season in full swing, most photographers are anxious to obtain the best slides they can from the negatives at their command, and therefore the question as to which is the best of the various processes is one which naturally arises. The majority of the slides sold in the shops are either by the wet collodion process or Woodburytype. Those by the former are very brilliant, and, therefore, well suited for lantern projection, but as a rule they are somewhat cold and not altogether pleasing in tone. Slides by the Woodbury process show equally as well on the screen, and usually are of a much more pleasing colour. The production of slides by the former of these two processes involves an intimate knowledge of wet collodion photography; for the latter a powerful hydraulic press as well as a knowledge of making the necessary gelatine reliefs are necessary.

Slides made by the collodio-bromide process are by no means inferior to those by the Woodbury method, as they have a similar transparency in the shadows, and the same may be said, though perhaps in a lesser degree, of those by the carbon process. There is, we think, very little question that by far the larger proportion of the slides that are produced by amateurs are made on gelatine dry plates. That is by no means surprising, seeing that the plates are sold ready for immediate use, are easy to manipulate, require no special knowledge, while the results obtainable on them are really excellent.

Having alluded to the methods most generally in vogue, we have reserved what we have to say with reference to albumen. Most of our readers are familiar with the beautiful stereoscopic transparencies for the stereoscope, formerly produced by Ferrier, and also by Soulin, many years ago. These were by the old albumen process, and they have not yet been surpassed, if equalled, by any of the more modern methods. The beauty of albumen slides is their extreme brilliancy, and excellence of tone, when thrown on the screen. The highest lights are represented by absolutely clear glass, while the shadows are of great depth, yet quite transparent, and of a rich brown or a very warm black colour. While the shadows appear so strong, they are really so transparent that printed matter may be read through them, even in the darkest parts. The albumen image seems to be more of a stain than an actual deposit of silver, which, of course, it actually is.

We shall here give full working details of the albumen process for the benefit of those who may desire to make a trial of it for their slides. The details may, at first sight, seem tedious and complicated to some, but they are not really so in practice; and the process does not require so much skill and experience as does wet collodion. In the earlier days of the process it was a ticklish one to deal with, as the plates, after coating with the albumen, had to be dried horizontally, during which time they were very prone to attract dust, which was really one of the greatest difficulties in working the process, since any particle of it would cause a spot or blemish in the finished picture. In the more modern method of working—that is, with a substratum of collodion on the plate—this trouble is obviated. We shall now proceed with the working details of the process.

The collodion best suited for the substratum is that which has been iodised some time—two or three months—and has become quite dark in colour. It should yield a somewhat porous film. In the old method of working the

process the albumen had to be whipped up into a stiff froth; but the following is the modern way of preparing it:

Take white of eggs, from which the germ has been removed, 10 oz.; glacial acetic acid, 30 minims; water, 1 oz. Mix the acid and water together, and then stir gently into the albumen with a glass rod, taking care not to froth it. When intimately mixed, allow to stand for a few hours, when a curdy scum or crust will have formed on the surface, which can be removed in a mass by the fingers. The albumen, which is now very limpid and clear, is filtered through a plug of sponge or cotton wool placed in the neck of a funnel. When filtered, add fifty minims of liquor ammonia .880, which will materially increase its viscosity. It is now iodised with the following:—

Ammonium iodide .....	50 grs.
Ammonium bromide .....	8 grs.

The iodised albumen will keep good for several months if kept in a well-corked bottle.

The glass having been made thoroughly clean and coated with collodion, as described in the articles on the wet collodion process by Mr. E. W. Foxlee (see pages 483 and 558 of the "B.J." this year), are put into a dish of cold water. If a good-sized dish is used several plates can be dealt with at a time. In this they are allowed to remain until they cease to appear greasy. A plate is then taken out and well rinsed under the tap, in case any trace of ether or alcohol still remain in the film; it is then well drained. Some of the albumen is then taken in a measure and poured along one edge of the plate and caused to flow over in an even wave, carrying the water before it into the sink. A second lot is then flowed over in the same way, and then a third. This may be drained off into another measure and used for the first application to the next plate, so as to economise the albumen. The plates as they are coated are placed in a rack to drain. When a number have been coated they are dried, singly, by holding them before a clear fire, but without altering the position in which they drained. In the drying, the plates should be made as hot as the hand can bear. This roasting prevents blistering of the film, which might possibly occur, in the development. All this work can be done in full daylight. The plates will keep good for years if kept dry.

The sensitising bath is as follows:—

Distilled water .....	10 oz.
Silver nitrate .....	1 oz.
Glacial acetic acid .....	1 oz.

After filtration, the bath is ready for use. The plates may be sensitised either in a dipping bath, or in a flat dish, but in either case they should not be allowed to remain in the solution for more than thirty seconds to a minute—the shorter time in summer and the longer in winter. The sensitising, it goes without saying, must be done in the dark-room. As the albumen is a very slow process, this need not be a very dark one: a single sheet of "canary medium" on a good-size window will be quite a safe light, and a very pleasant one to work in.

After the plates are removed from the silver bath they are put to soak, with occasional agitation, in a tray of distilled, or boiled, water, to wash out the free nitrate of silver from the film, and then well rinsed under the tap, to get rid of the last traces of it. They are then placed on a rack to drain and dry. The plates, after sensitising, will keep for many months, so that a good stock may be prepared at a time. If, after the final rinsing, they are flowed over with one grain to the ounce solution of gallic acid they will keep good for two or three years if kept under the same conditions as gelatine plates are. The preparation and sensitising of the plates may appear slow and tedious operations, but by working systematically, with good-size dishes, from a dozen to twenty plates may be prepared in an hour—the sensitising takes up less time than the albumenising. It may be mentioned here, that, although collodion is used, the process is quite different from the collodio-albumen process. In that the collodion is sensitised in a silver bath before the albumen is applied. In this it simply acts as a substratum, and plays no part whatever in the formation of the image. One of the greatest advantages of this substratum is that if any particles of dust settle on the plate the albumen, as it dries, forces them into the collodion film, where they remain inert and do not yield blemishes, as they would do if the albumen were on the bare glass, as in working according to the original method.

The exposure, development, and toning of the albumen transparencies must be deferred until next week's article.

## GRAPHIC TELEPHOTO LENS CALCULATIONS.

In a former article ("B.J.," May 5, 1905) the writer dealt with the subject of graphic lens calculations, showing how the equivalent focal length of any ordinary photographic objective, the greater and lesser conjugate foci for a given size of image, etc., could be ascertained by a simple geometrical method without the aid of arithmetic. It has been suggested that further examples of a similar kind would prove helpful to many. The following problems, which deal with the various factors affecting the use of the telephoto lens, while perhaps of more limited usefulness than the preceding data, are capable of being turned to good account; as, for instance, when the occurrence of several fractions renders the arithmetical method troublesome, or when it is desired to check and verify the latter. They may also be suggestive to those who wish to purchase or adapt a telephoto combination for some special purpose, and are not quite sure what is required. The geometrical construction throughout is based on the well-known rule for finding a fourth proportional by the aid of similar triangles.

### PROBLEM I.

To find the camera extension necessary for any given magnification.

Draw two lines AB and AC (Fig. 1) at any convenient

Fig. 1.

angle. Along AB mark off, to any suitable scale, AD, AE, and AF, equal respectively to the unit of the scale employed, the focal length of the negative lens, and the magnification

Draw two lines AB and AC (Fig. 5) at any convenient angle. From A, along AB, mark off AD equal to the focal

length of the positive lens. From A, along AC, mark off AE equal to the unit of the scale employed, AF equal to the magnification, and AG equal to the focal length of the negative lens. Join E and D, and through F draw FH parallel to ED. Through G draw GI parallel to FH. Join E and H, and through I draw IJ parallel to EH. From J mark off JK equal to AD. Then GK is the required separation.

$$s = \frac{f_1 f_2}{F} + (f_1 - f_2).$$

$$F = f_1 M.$$

Proof of geometrical construction:—

$$AD = f_1, AF = M, AG = f_2.$$

$$AH : AD :: AF : AE \therefore AH = AD \times AF = f_1 M = F.$$

$$AI : AD :: AG : AE \therefore AI = AD \times AG = f_1 f_2$$

$$AI : AH :: AJ : AE \therefore AJ = \frac{AI}{AH} = \frac{f_1 f_2}{F}$$

$$AK = AJ + AD = \frac{f_1 f_2}{F} + f_1.$$

$$AG = f_2, GK = \frac{f_1 f_2}{F} + (f_1 - f_2).$$

i.e., GK = separation.

#### REMARKS ON FOREGOING PROBLEMS.

Although, for considerations of space, all the annexed diagrams are drawn with the lines AB and AC at a rather acute angle, it is preferable in actual practice to make the two lines nearly at a right angle. The reason for this is that, in the latter case, there is less likely to be any mistake regarding the points at which the various parallels cut the base line, as might easily arise when one line meets another at a very acute angle. It will be noted that some of the problems suggest useful alternative formulæ. To quote a very obvious example, since  $F = f_1 M$  (Problem V.), it is evident that

$$M = \frac{F}{f_1}, \text{ and } f_1 = \frac{F}{M}.$$

The interested worker will be able, by an attentive study of the proportional principle involved, to find further instances where a given formula may be made to serve several purposes.

A. LOCKETT.

## RECEPTION-ROOM CONTRASTS.

[In the current issue of "Wilson's Magazine" (New York) we press photographer, and evidently a keen observer of men and must resemble that of one here, and therefore the impression of those in professional establishments.—Eds. "B.J.P."]

To write an anonymous letter is generally esteemed a mean and ungentlemanly thing to do. To travel 'round the country *incognito* is practised by the greatest and most exalted of people—so fashion sets the seal of her permission on a quibble. At the same time, while I have been guilty of doing some investigating *incog.* which would have been less successfully accomplished had I announced my purpose, I trust my readers will not think too badly of the proceeding, inasmuch as what I found out benefits me not at all, may benefit some who hear of what I saw, and hurts no one, since I shall not, either now or hereafter, mention any names.

I visited eleven different galleries, located in two cities, to see what I could learn from the standpoint of a possible customer, and what things I should find, or what indications I should come across, which would naturally demand my custom. With a couple of exceptions the work shown me was, in all cases, excellent. That is, photographically, it was good—clear negatives had been used to make handsome, clean, bright prints, which are artistically and pleasingly treated, either in a mount or a frame. As my little trip was not to determine the relative excellence of these eleven photographers, the one to the other, but to see what their externals would say to a possible customer, I lay aside all questions of good work. All the photographers I visited—with the exceptions noted and to be told of later—were good photographers. All had, presumably, a good trade; and all, let us hope, were engaged in delivering good work for money taken—as good as the samples they showed.

#### The Need of Good Appearance.

The first gallery I visited was on the sixth floor of an office building. I took the elevator and stepped from it immediately into the reception room. The general impression was very pleasing. The room was partly divided—by pillars and hangings of dark Japanese lattice-work—into several alcoves; there were a number of comfortable chairs, and the walls were fairly well covered, although not crowded, with large examples of the proprietor's work; comparatively small and inconspicuous counter and showcase were in one corner; there were windows on two sides of this room. There were several people waiting when I got there, and I had ample time to observe the receptionist and

find an article by Mr. C. H. Claudy, a well-known writer and things. At bottom the management of a studio in the States created on our author may be usefully re-conveyed for the benefit

her methods before she got around to me. There was nothing to quarrel with in her manner, which was polite and cordial, but she spent no more time than was absolutely necessary on each customer. Meanwhile I noticed a few things which became plainer as I looked: the velvet was badly worn off two of the chairs; three out of seven framed pictures hung crooked; a part of the Japanese woodwork had become broken, and its jagged end still protruded unfixed; there was a thin layer of dust on top of a table; a large portfolio, conspicuously displayed, had some magnificent photography in it, marred with poor and very dirty, and, in some cases, torn mounts. This studio is one of a chain of several in several cities. The owner leaves it entirely to his operator, receptionist, and dark-room man. I understand he visits it once or twice a year. Naturally things run down. Now this place has a good trade, but it misses a better one by a lack of attention to details and a laxness which would not be tolerated in a home of any pretensions. Yet it is offering itself as a temporary resting-place to its customers and expects the impressions of its undeniably good work to overcome the insidious impressions of the somewhat run-down furniture and fixtures.

#### The Money Value of Tact in the Reception-room.

The next studio I went to was exactly the reverse. I looked in vain for anything not spick and span. The fixtures displayed were not so many in number nor so great in size, but every one was a new print—clean and attractive, and every one showed something different from the others; the receptionist was a charming young woman, somewhat plain of feature, but very engaging in manner, professing interest in some small styles, and she could hardly do enough for me or other customers present or who passed through while I was there. I saw her sell an extra half-dozen of enlargements to a woman who had already paid for two dozen half-length panels, and she did it in such a way that the customer left enchanted with her bargain. A somewhat poorly dressed and obviously ignorant woman was waited upon strictly in her turn and received every bit as much courtesy and the same pleasant smiles that the other customers had had. I will not say she had so much time spent upon her.

but she left with a smile, and she left well treated. If she has any money to spend, she will spend it there where no account was taken of her dress or looks, but where she was greeted with a smile and an interest taken in her wants. Yet the showcase of this studio has not been changed for three months to my certain knowledge. I suppose they haven't time. They do a big business and a paying one; but I have never known any concern that had more work than it wanted all the time.

Studio No. 3 is considered possibly a little old-fashioned, but very reliable. Its show-cases and its wall decorations are the enlarged negative, platinum-prints-of-celebrities style. The furnishings are plain and prim, but clean and neat. The general impression is that all the attention goes to the work and none to the frills. No shop-girls or society women come here. A large, even trade of middle-class people, who have bought here for years, and will do so to the end of time, form its patronage. There are two receptionists, pleasant-mannered young women, who do what they should and sell you what you want; but neither is to be compared for a moment to the little woman in No. 2 in ability or in paying power to the studio.

#### The Down-at-the-Heel Business

Studio No. 4 was a sad sight. The name over the door is old and well-known. It has been over a photographer's shop, from father to son, for half a century. At one time it was one of the biggest businesses of its kind in the country. It is so no longer. On the counter in the bare reception-room is a pile of prints, pressing flat beneath two books and a dusty paper-weight. The wall about the telephone is scribbled full of pencil numbers. A man's coat and a pair of cuffs are upon a chair. Four pictures sit dolefully upon the floor with their faces turned out—two more have their backs to the observer. A pompadoured girl in a soiled apron spots prints at a window. A man in shirt-sleeves is ticking negatives by another window. The girl doesn't see me until I cough, and then she rises without a smile to her work. Almost wordless she shows me what she has—names the prices—that is all. The general impression is one of lack of interest, mould, deadness. A woman comes to return proofs as I leave. She complains about something. I do not quite hear what. I do hear the man arguing with her while the poor receptionist, robbed of her job, stands to one side helpless. I know for a fact that the work done here is beautiful, for I have often seen it, but I am afraid its quantity has largely diminished, and by a process of dry rot will presently die away entirely. When the proprietor has no pride in the appearance of things which tell his story to newcomers, you can be sure he is either trying to sell or commit business suicide.

#### The Feminine Note.

The fifth gallery I went to is owned and operated by a woman. She has two women assistants in sight, and I suppose more out of sight. She does essentially woman's work and does it well, but she does not draw the line at men at all. But she very frankly tells me—the receptionist has brought her in to interview the unusual man—that she is more successful with women and not much used to posing men. Everything about the place is as neat as a new pin and almost in good taste. But there are too many spindle-legged gold chairs, too many curtains and hangings, and entirely too much bric-a-brac for real beauty. Although each individual thing is real, and the colours harmonize, the general impression is "stuffy." Not being a woman I can't say but what this is attractive to them; but I think not. I imagine it repels many who want work done. Another thing I notice is that the work turned out is poorly finished. The negatives were good, the prints all right, but they are carelessly trimmed and mounted and spotted in some cases. This is bad business with orders, but in samples it is suicide.

#### Professional Photography de Luxe.

Gallery No. 6 is on a grand scale. There are no less than three reception-rooms, each larger than the last and all are sumptuously decorated.

There is a great deal of heavy red plush, and chain-armour and battle-axes and suits of armour—there is a multicoloured half-tent in one corner of one room and the lighting is subdued throughout. The receptionists are very busy. They show me what I ask for, after telling me they do not do that class of work. They evidently take me for what I am, a not-at-all wealthy prospect and rate me accordingly. I do not get enough attention to make me feel anxious for more. A small boy who has a package on his hand waits long for notice and is still waiting as I leave. A man whom I know by sight rushes in, fur-coat thrown back, diamonds on his shirt, wealth radiating from every pore. It takes two girls to wait on him, while several of us stand around and wait. I understand this gallery does a huge business with wealthy people and hasn't time to bother with small orders and small customers.

But I want to make a point that anyone can heed or not, as he sees fit. There is such a thing as declining a piece of work because there is not enough in it, without giving any offence. There is another way which makes the customer feel as if he would like to wreck your place. When I go to a big printery to have a hundred business cards printed, and they take as much interest in it as they should, and are polite and deliver goods on time, I am apt to send them the first big job I handle. When I go to another printery and he growls out: "Full up; haven't time to fool with such little jobs as that," and puffs smoke in my face and turns his back, I don't feel much like carrying my orders there. A photographer may readily decline to do work he knows doesn't pay him, as crowding out bigger jobs; but if he does it in such a manner as to make an enemy or hurt someone's feelings, however negligible a factor that someone may be, he is pulling bricks from his own foundation wall. Many a tale gets up the backstairs, and there is many a tradesman who loses trade—photographer or butcher, it matters not—because My Lady lends indulgent ear to the complaints of her maid. You can't afford, I don't care how big you are, to be any thing but courteous and polite, and I mean the true courtesy and the true politeness which make friends; not the technical politeness and courtesy which consist only in not kicking your customer downstairs.

#### A One-Woman Business.

The next gallery I go into is uptown. It is a little place and the lady who waits upon me is proprietor, receptionist, retoucher, and operator in one. Her little reception-room is a homey, living room—with never a pretence and never a frill, but it is genuine. Her work is good, for the prices she asks, and she tells me it is getting better. She has a good trade among a rather low-priced class of work, but it evidently pays. I have less opportunity for observation here than elsewhere as there is no one there when I come and have to talk business or get out—which I do.

Gallery No. 8 is a mass of confusion. It is the rush time of the day and a dozen customers are clamouring for attendance, and a girl, the owner, and an office boy are distractedly trying to wait on all at once. The furniture is badly arranged—the counter and showcase are where they get the worst possible light and there is considerable calling in and out of the operating-room between the owner and "Jake," presumably the operator. Instead of taking his customers one at a time, and giving each his undivided attention, this misguided man is endeavouring to sell three women three different kinds of photographs, and each is wanting to know why he isn't recommending to her the kind he is telling her neighbour she should take. As one is large and stout, the other tall and thin, and the third of impossible profile, it is obvious why; but the poor man can't explain and gets all involved and suspicion sits upon the faces of all three.

A charwoman scrubbing down the steps in the middle of the day only accentuates the note of bad management.

My inspection of these places was, of course, but superficial,

and is in no way final; but just you remember that your customer's inspection is superficial too, and final only as concerns herself! It is what she sees and hears and the way she is treated in the first five minutes of her acquaintance with you that determines if she likes you or not—and if she doesn't some other fellow gets the money. I have never realised as I did after

this little trip how much it pays to put attention in external is a business where impression at the outset is so much of the game. I really believe it will pay any proprietor of a gallery to visit himself half a dozen others, where he is unknown, in the same critical spirit which I took with me. It is certainly worth a trial.

C. H. CLAUDY.

## RESEARCHES ON THE LATENT IMAGE BY MEANS OF PLATES FREE FROM COLLOID.

[A recent address before the Photographische Sektion der Naturhistorischen Gesellschaft of Nurnberg. Dr. Weisz, who writes from the Consortium für Elektrochemische Industrie G.m.b.H., Nurnberg, has prepared the following popular account of his experiments.]

WHILE it is universally known that the exposure of silver bromide involves a chemical process, the exact nature of the change is still very obscure, though it is certain that the silver bromide, on exposure to light, loses its bromide, which is transferred to the free state. If pure silver bromide is exposed in a small closed glass tube to sunshine, it blackens and evolves a heavy brownish vapour, which has the smell and chemical properties of bromine. If the silver bromide is imbedded, as it is in dry plates, in the form of small grains in gelatine, the bromine does not then escape into the air, but remains combined with the gelatine, the products of the reaction being thus a bromide which has lost bromine and bromised gelatine. The bromide-lost bromine is the material of which the latent image, as formed in plates and films, consists, and the following experiments were made in the hope of throwing light on its character and composition.

The chemistry of silver teaches us that there is but one compound of silver and bromine containing less bromine than bromide of silver. It contains two atoms of silver to one of bromine, and is usually designated by the name of silver sub-bromide. No compound poorer in bromine is known to exist, so that the next stage in the reduction process of silver bromide is metallic silver itself. A good deal of controversy has taken place as to whether sub-bromide or metallic silver is the substance of the latent image. The following experiments were undertaken with plates free from any colloid body, such as gelatine, as gelatine and other colloids are of such chemical properties that they may act upon the bromide of silver above mentioned formed in light. The glass plate was laid on the bottom of a dish placed horizontally, the surface of the plate having been ground to a fine matt. A thin cream of freshly precipitated silver bromide prepared from silver nitrate and hydrobromic acid in the dark was poured upon this glass plate. In five to ten days the silver bromide had firmly attached itself to the matt side of the plate. The clear solution was poured off, and the plate removed from the dish and dried. The finished plates are pure yellow, have a thick appearance, and are 100 times less sensitive than the yellow label Schleussner plates. The silver bromide adheres so firmly to them that they may be exposed, developed, and even fixed as usual, and in other respects can be treated as ordinary photographic plate.

If the latent image consists of metallic silver it should be possible to develop an *unexposed* colloid-free plate on which by a suitable chemical method metallic silver has been first distributed instead of by exposure. In order to put this to the test, use was made of the fact that a solution of ferrous sulphate precipitates finely divided silver from silver nitrate solution. One end of the colloid-free plate was dipped in silver nitrate solution and the latter allowed to dry up. A subsequent dip of the same end of the plate was then given in ferrous sulphate solution of suitable strength so that a scarcely visible pale grey fog was deposited on the plate, which fog represents the latent image formed without any exposure. It consists of microscopically small particles of silver which, on account of their minuteness and fine division, may be called a silver *germ*, a name which suggests the facility with which such germs may bring about crystallisation from a super-saturated solution. One may refer here to a similar phenomenon which takes place in the case of Glauber's salt (sodium sulphate): a minute fragment of the crystals will bring about the crystallisation of a super-saturated solution. It is in this sense that the finely divided particles in the colloid-free plate are

here designated as germs, because with them the development process proceeds as the crystallisation with the Glauber's salt germs. The plates are now thoroughly washed, dried, and developed with metol. The latent image is thus converted into a dense image of metallic silver (Figs. 1 and 2), in which A is the untreated plate B with the silver germ on the upper part, C the same plate after development. Fig. 1 shows the appearance viewed by direct light Fig. 2 that by transmitted light. Both were obtained by photographing the original plates on yellow-sensitive dry plates. In the case of gelatine dry plates the above experiment yielded a similar result.

From these results it should follow that the latent image can consist of metallic silver, and many would suggest that such composition is proved by the above experiment. Although this is the case, it is possible that the latent image does not consist of metallic silver. If metallic gold, platinum, iridium, osmium or rhodium or sulphide of silver is formed in a suitable chemical manner in the unexposed film of a plate free from colloid, a latent image is formed which can be rendered visible with the metol developer. (The plates reproduced in Figs. 1 and 2, answering to these conditions, are exactly similar.) That metallic silver can be thus the substance of the latent image does not, however, prove that it actually is the substance, inasmuch as the developable properties conveyed by metallic gold, platinum, etc., might be taken to prove that the latent image consisted of these substances. Nevertheless these facts supply an explanation of the development process to which we shall come later.

That the latent image does not consist of metallic silver is shown by the following:—If a colloid-free plate in which, as above described, a latent silver image has been obtained is placed in concentrated nitric acid, the metallic silver dissolves in the acid and the plate can no longer be developed with metol. If, however, a colloid free plate be *exposed* and then brought under similar conditions<sup>1</sup> into the same nitric acid, the metol developer will give rise to a vigorous image.

This experiment shows that the substance of the latent image is different from metallic silver, and withstands concentrated nitric acid.<sup>2</sup>

We will now see to what conclusions we are led from the permanence of the latent image towards nitric acid. Metallic silver evidently need not be any further considered as a constituent of the latent image. If sub-bromide of silver forms the latent image we should be able to obtain by chemical means a sub-bromide possessing the same properties as the latent image, especially in regard to its permanence in strong nitric acid. Silver sub-bromide has not hitherto been prepared, but only silver sub-chloride.<sup>3</sup> The great chemical similarity of chloride to bromide of silver suggests that conclusions as to the sub-chloride may be applied to the sub-bromide. Silver sub-chloride does not resist strong nitric acid which extracts the silver from it. Consequently, silver sub-chloride consisting of two atoms of silver to one atom of chlorine, and thus richer in silver than the normal chloride (consisting of one atom of silver to one atom of chlorine), is made similar to this latter by nitric acid. How-

<sup>1</sup> I use a nitric acid of 1.3 sp. gr. for one hour.

<sup>2</sup> This shows the advantage of using a colloid free plate; a gelatine plate would separate from the film in acid of the above strength.

<sup>3</sup> Heyer investigation of the hypothetical silver sub-chloride inaugural dissertation, Leipzig bei Glanesh, 1902.

ever, the action of the nitric acid may remove not the whole excess of the silver, but only the greater part thereof. After the extraction with nitric acid there remains behind a substance which still contains from 1 to 2 per cent. more silver than silver chloride, which substance gives up no further silver to nitric acid. One may assume that the silver sub-bromide behaves towards nitric acid in the same way.

We saw that in the case of tubes exposed to sunlight the silver

Fig. 1.

bromide lost bromine on exposure, and was converted into a substance containing less bromine and more silver than the unexposed silver bromide. We also saw that this substance withstands strong nitric acid. Finally we found that all "compounds" of silver and bromine (prepared by chemical or synthetic means) which are richer in silver (poorer in bromine) than bromide of silver (and metallic silver itself), can be attacked by concentrated nitric acid until there

Fig. 2.

is left a compound which is 1 to 2 per cent. richer in silver than the unexposed silver bromide. Hence the substance of the latent image is identical with the substance thus produced by the extraction of the silver from sub-bromide of silver with nitric acid. A "compound" of this kind—that is to say, one which contains 1 to 2 per cent. more silver than normal silver bromide—is no true compound at all in the chemical sense. Chemical compounds, as is well

known, are characterised by the fact that in their different combinations (silver bromide and silver sub-bromide) the same elements (bromine and silver) exist in definite simple proportions. Sub-bromide, for example, contains for each gramme of bromide exactly twice as much silver as silver bromide. A compound in which for 1 gramme of bromine there is but 1.02 times more silver than in silver bromide, as in the above-mentioned case, is no true chemical compound. Modern chemistry recognises these compounds as solid

Fig. 3.

solutions in the present instance of silver bromide and silver sub-bromide. All "compounds" of this kind do not form solid solutions, but special consideration of them is not fitting in this place.

The representation of a solid solution is not easy. A good idea of the meaning of the term may be had from consideration of the composition of brass which is prepared from molten zinc and copper,

Fig. 4.

and in both the molten and the solid state contains these two metals dissolved one within the other. We must therefore imagine sub-bromide of silver and silver bromide dissolved together in the substance of the latent image as are the zinc and copper in brass. So the examination of the substance of the latent image with the aid of colloid-free plates has led us in a simple way to discover that it consists of a solid solution of silver sub-bromide and silver bromide

containing not more than 2.7 per cent. silver sub-bromide and not less than 97.3 per cent. silver bromide. The same colloid-free plates have made it possible to carry out two experiments which throw some light on the process of development.

A colloid-free plate was exposed under a photometer, and after complete exposure two gradations were rendered visible as in fig. 3a. The plate was developed in metal, when six photometer gradations then appeared, fig. 3b. On an attempt being made to apply concentrated nitric acid the whole image disappeared, and the two degrees originally visible alone remained, fig. 3c. On now washing thoroughly and developing once again the whole image, as in fig. 3d, again becomes visible, and the same process was repeated a third time and several times further until the plate fogged.

The second experiment was made as follows:—Germs of metallic silver were deposited on the colloid-free plate as described at the early part of this paper, where it was mentioned that strong nitric acid dissolved the germ entirely away. If the plate, after complete solution, is developed, nothing is obtained. But if after deposition of the germ one develops and then dissolves for the same time and under similar conditions in the nitric acid, there remains behind a scarcely visible fog on the parts where the germ has been deposited, and this is capable of being once and several times developed as in the previous experiment (see fig. 4), where A is the silver germ dissolved and developed, B the germ developed, C the germ developed as in B and dissolved after development, D the germ portion shown in C dissolved after development and again developed. Figs. 3 and 4 are hand drawings from the original plates. The first experiment shows that the solid solution of sub-bromide in silver bromide which forms the latent image is not appreciably altered by photographic developers. It withstands oxidising agents such as nitric acid, and reducing agents such as developers, and is not reduced by the developer to metallic silver. The second experiment shows that the silver bromide on development is reduced not only to silver but also to sub-bromide of silver, which forms with the unexposed silver

bromide a solid solution. The silver is again removed from this solid solution by the action of nitric acid, leaving a 1 to 2 per cent. excess.

As regards the processes carried out by development, a consideration of the foregoing experiments leads us to represent them somewhat as follows:—On an exposed silver bromide plate being placed in the developer there is dissolved a very small quantity of the unexposed silver bromide in the developing solution, inasmuch as silver bromide is very slightly soluble in water. The dissolved silver bromide is partly reduced by the developer to metallic silver which at first remains in solution. If there were no solid solutions of sub-bromide of silver and silver bromide present (that is to say exposed silver bromide) nothing more would happen. (An unexposed plate does not blacken in a developer.) The solid solution of sub-bromide and silver bromide, which, as already shown, is not altered in the developer possesses, however, the property of forming further solid solutions with metallic silver and attracts the dissolved metallic silver to itself from the developing fluid. Gold, platinum, iridium possess the same property, and an explanation is thus given of their "developability." Hence fresh metallic silver is formed from the dissolved silver bromide, and fresh silver bromide dissolves from the film into the solution. This change is repeated again and again. Wherever solid solution of sub-bromide and silver bromide had been formed (on the exposed portions) does more and more silver separate—in other words, the plate develops. Regarding the second experiment, it must not be forgotten that the silver bromide dissolved into the developing solution is also reduced to sub-bromide, and it must, moreover, be remembered that simultaneously the silver sub-bromide enters into the solid solution with the substance of the latent image, and this solid solution includes silver sub-bromide. Once metallic silver has separated it acts upon the metallic silver dissolved in the developing solution just as a crystal of solid sodium sulphate on a super-saturated solution of that compound and helps in this way to the development process.

DR. HERMAN WEISZ.

## THE STRENUOUS LIFE.

[A not very exaggerated picture of what is required of the Press photographer appears in a recent issue of the "Daily News," where a writer, Mr. W. M. Duckworth, considers the news photographer among other new types to be found in London. The article which we reprint below will at any rate give a rough idea of the temperament which must be the possession of the successful Press photographer, to say nothing of a "collapsible £60 pocket camera."—EDS., "B.J."]

To be a professional snapshotter, a news photographer, a "live" picture-taker, or whatever name you choose to bestow upon the new professor of Fleet Street sensationalism, is to be a young man of infinite daring, a strategist born, a detective bred. He must possess inordinately that craving which inspires one to get the better of one's "ellow-creatures—to risk all but life and honour for the sake of getting a photograph that will "tell the tale."

He was unknown a few years ago. The public taste has brought him to the forefront, and now a little army of a hundred of them is to be found when the sun has set, in their dark rooms in Fleet Street attics. Grit is the motto of the new race of newspaper photographers. He is an indispensable factor in modern journalism. His life is a succession of shocks and thrills—a continuous battle to snap that which seems unsnappable, and which public exigencies often demand should not be snapped. But the man is yet unborn, the thing yet uncreated, that the professional photographer cannot drag into the zone of fire.

### The Uses of an Outfit.

There is nothing on earth quite like a peep into the daily life of one of these young irrepressibles. I sat yesterday in the studio of one of the most daring of the species, enthralled by the story of some of his recent adventures. This is a young fellow who swarmed the flagstaff on top of the Hotel Cecil one night with a camera under his arm to get a nocturnal study of London. He is a man typical of his profession, who goes about with a collapsible £60

camera in a secret pocket of his coat and a tubular aluminium tripod which he can use either as a walking-stick or a weapon of self-defence. He has travelled all over the world on the great quest of news photography. Not long ago he smuggled a camera into the forbidden village of Mittupuhaka, on the banks of the Ganges, near Calcutta, and opened fire on the Hindoo fakirs. They resented his presence and hounded him out of the village in their hundreds. He escaped with his life by hiding on the banks of the river.

### "Bounders" among Press Photographers.

Royalty is not averse to the newspaper snapshotter in moderation. During the recent festivities at Sandringham the King saw the local inspector of police trying to wrench the camera away from one of these gentlemen. His Majesty sent an equerry to restore order, and commanded that the photographer should be allowed to take what pictures he liked. The King has often intervened in this wise between over-zealous policemen and the Press photographers. On this occasion the Queen showed her sympathy with the snapshotter by inducing the King to face the camera, smoothing down the lapels of his Majesty's coat herself. Moderation in the presence of Royalty is everything. There is the story of the impetuous photographer who had the audacity to climb over the fence at Sandringham and snapshot a member of the Royal family while taking a quiet stroll in the grounds. He was instantly seized, escorted back by two policemen to Wolferton Station, and sent home to London with a cancelled permit.

By the art of simulation, and by his own wit, the professional snaphotter has provided the public with many a valuable picture. Professional rivalry has forced him to disguise himself. At the Brinsmead golden wedding celebrations in North London, the snaphotter found himself outside the private residence of the famous pianoforte maker without a permit. His eye fell on a butcher boy, with whom he exchanged clothes. The meat was taken out of the basket, the camera substituted under a white cloth, and the snaphotter, in blue smock and cap, went boldly up to the tradesmen's entrance, and so the trick was done. This was the same genius who took a series of pictures of the "Nimrod" in the East India Dock before she set out under the command of Lieutenant Shackleton on the Arctic expedition.

### Strange Story of a Camera!

The policeman at the dock gates had orders to exclude any man carrying a camera. Anybody else would be admitted. "I got out of the difficulty," said this adventurer, "by pulling my camera to pieces. There were six pieces, and I passed that policeman six times, each time with a piece in my pocket. Then I put my camera together again, erected a stand of my own, and fired away unobserved. When I came out through the dock gates I discovered that the authorities had repented of their stringency, and had granted permission to the photographers at the last moment."

### Adventures for Photographers.

Earthquakes, volcanoes, tidal waves, big game-hunting in foreign climes, wars and internecine struggles, eclipses of the sun and moon—these things come within the sphere of the snaphotter. Patience is part of his catechism. He has been known to wait for hours shoulder high in a swift-flowing river to get a picture of a kingfisher in its nest. He must be a man of unbounded resource, without which he will be reckoned a failure. When Miss Edna May was married from Ascot there was a stampede of snaphotters to secure a negative of the wedding presents. But permission to enter the house was denied them. A youth, however, crept under the shadow of the house and inserted his camera in an open window where a glimpse of the presents could be got. He opened his shutter, went back to a place of safety, leaving a costly camera at the mercy of any chance finder, and after an hour's exposure returned for his picture, which was worth many pounds in the photographic market.

Portsmouth, Windsor, and London were the photographer's paradise during the Kaiser's visit. When the Imperial yacht berthed at Portsmouth Jetty, a snaphotter crept under the engine of the Royal train and crawled underneath the carriages till he found himself at the Royal saloon. He was discovered by the guard, and had to beat a retreat, but not until he had taken a picture of the Kaiser at close quarters. In Oxford Circus, when the Kaiser halted to receive the Mayoral address of welcome, a photographer in the crowd dangled his camera on the end of a telescopic aluminium pole, and released the shutter by means of a long pneumatic tube. It hung almost above the Imperial landau, and naturally the Kaiser eyed it with suspicion.

### The Flashlight Press Man.

The daring of these men has reached the stage when it becomes a necessity to jump in the way of moving vehicles containing celebrities at the risk of being run over. This was done when the first Embankment tram passed over Westminster Bridge at night time. The photographer leaped in front of the tram when it was going, and left it to the driver whether or not he should be run over. The driver, of course, instantly pulled up, there was a blinding flash of six ounces of magnesium, and a remarkable flashlight picture showing Mr. John Burns on the footboard was secured.

The noble army of photographic newsgutters is distinguished by the youthfulness of its members. The oldest Press photographer, who is not yet fifty, has given the profession up in despair. He is living now in glorious retirement in a remote village in Devonshire.

**PENROSE'S PICTORIAL ANNUAL.**—We regret that an error was made in the price of the "Process Year Book," reviewed last week. The Annual is issued at 5s. net, not 7s. 6d.

## Photo-Mechanical Notes.

### Half-Tone Screens

A PATENT (No. 26,012, 1906) has been granted to Mr. D. Cameron-Swan for a cross-line screen similar to those in ordinary use in the manufacture of half-tone blocks, in so far as relates to the crossing of two or more sets of lines at a right angle or any other suitable angle or angles, but dissimilar to such cross-line screens in that each series of parallel lines differs from any crossing it in respect to the relative thickness, and (or) distance apart of its lines as compared with those in the crossing series of lines, provided only that such shall contain uniform aperture throughout.

The screen is used for producing the negative in a similar manner to that commonly employed in making half-tone blocks, except that the diaphragm or diaphragms used in the lens have an elongated aperture or apertures so placed that the longer axis (or axes) of the aperture or apertures is (or are) parallel to the thicker or more predominant series of transparent spaces between the lines in the screen, so as to cause continuity or partial continuity of the predominant lines in the half-tone block.

## Exhibitions.

### HOVE CAMERA CLUB.

A PROVINCIAL Photographic Exhibition to which some 200 artists contribute nearly 600 pictures, not only of great technical excellence, but also of high artistic worth, may indubitably claim to be successful in the achievement of its object and aims; and the Hove Camera Club has the satisfaction of knowing that the figures given represent briefly the result of the Exhibition held at Hove Town Hall on December 11 to 14.

The Open Classes included over 300 examples of photographic art, and the successful competitors for the Club's plaques were C. H. Hewitt, with his "Flecked with Sunlight"; R. Dührkoop, with a striking portrait-study of "Hermann Gathker"; S. G. Kimber ("The College Cloisters"), A. Marshall, A.R.I.B.A.; Alfred Taylor, with "The Life History of a Kingfisher"; Miss H. Stevenson; Mrs. G. A. Barton ("Little Paul"), and J. B. Johnson, with "After the Day's Work." R. Hancock and S. E. Ward gained the awards in the Open Lantern-Slide Classes, the former by his set of Spider Studies, and the latter by his treatment of "Moonrise" over the sea.

The pictures in the Club Classes were of a high standard of excellence, and on the authority of Mr. R. Child Bayley, who judged the work, even surpassed those in the Open Classes in respect of architectural studies.

The Club "champion" this year is, without doubt, Victor E. Morris, who not only secured two plaques for landscapes and two more for his architectural picture, "Looking into the Cloister," and a set of lantern-slides, but also carried off the "Hounsom" Challenge Salver for the best picture in the Club Classes with a study of "The National Gallery," in which he displayed his noteworthy ability for obtaining delicate atmospheric effects.

Notable among the other successful Club exhibitors were E. W. Pannell, whose "Portrait of a Lady," with its tender half-tones, found an energetic contrast in his "Study" of a lady's head, with its rich depth of transparent shadow; E. Munt ("A Moorland Scene"), R. T. Alderton ("Poppies"), Stanley Read, the Club's Hon. Secretary, who took a plaque for his set of Lumière Autochrome Lantern-Slides; Col. Crawley; and Miss Best.

A Loan Collection of eighty fine examples of Modern Photographic Art from the Salon and Royal Photographic Society's Exhibitions formed an admirable addition to the attractions of the Show; and the display of the R.P.S. 1907 Lantern-Slides, together with those entered for competition, provided an interesting entertainment, which was several times repeated.

The Exhibition was opened by the Mayor of Hove (Captain A. B. S.

Fraser, J.P.), who was thanked by Mr. A. R. Sargeant, the enthusiastic President of the Club, for thus giving his official recognition to the Club's most useful help in educating local artistic taste.

Illustrated lantern lectures were given on three evenings of the Show, and were much appreciated by large audiences. Dr. E. J. Spitta's graphic account of the application of the cinematograph to scientific purposes, Mr. Harvey Piper's description of "Two Benedictine Minsters" (Norwich and Gloucester), and Mr. A. H. Dunning's notes on a tour "Homeward Across the World," from Singapore to England, gave alike many opportunities for interesting instruction, and for the exhibition by Messrs. Sanders and Crowhurst of some fine illustrative slides.

The Hove Camera Club may thus be justly satisfied with this, its 12th annual show, which should be the means of adding largely to its present goodly list of over one hundred members.

#### HULL PHOTOGRAPHIC SOCIETY.

THE annual exhibition of members' work, which was held from December 4 to 7, would appear to have been the most successful show yet organised by this enterprising society. The majority of the exhibits, of which there were more than 200, were bromide enlargements, toned to various shades of sepia, and bearing evidence to the fact that the cultivation of the pictorial side of photography received its full share of attention, though not at the expense of technical excellence. The exhibits also included a collection of colour prints and Autochrome transparencies, some by members of the society, and some lent by well-known workers in the various processes of colour photography. An attractive programme was arranged for each evening, including exhibitions of Autochrome lantern slides, and lectures by Messrs. Thos. E. Green and Alex. Keighley, the latter of whom devoted some considerable time to the preparation of a report on the exhibition for the benefit of the members. On the whole the exhibition was pronounced on all sides to have been an unqualified success, and will have not only fully recompensed the secretaries and others for the amount of hard work entailed, but will also doubtless have given a fresh stimulus to the society as a whole to in no way relax their efforts, but to resolve to go "one better" next year.

#### FORTHCOMING EXHIBITIONS.

December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

January 14 to 28.—Glasgow Southern Photographic Association. Entries close January 4. Sec., W. Bryce, 29, Somerville Drive, Mount Florida, Glasgow.

January 30 to February 1.—Nelson Photographic Society. Entries close January 20. Sec., Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

February 5 to 7.—Borough of Tynemouth Photographic Society. Entries close January 26. Sec., J. R. Johnston, 29, Drummond Terrace, North Shields.

February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

February 19 to 21.—Longton and District Photographic Society. Entries close February 8. Sec., T. Mottershead, 32, Stafford Street, Longton.

February 20 to 22.—South Manchester Photographic Society. Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.

February 23 to March 2.—Birmingham Photographic Society. Entries close February 8. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.

March 4 to 7.—Ilkeston Arts Club (Photographic Section). Sec., A. Smith, 11, Graham Street, Ilkeston.

March 7 to 14.—Leicester and Leicestershire Photographic Society. Sec., Lewis Ough, F.C.S., Fernleigh, St. James's Road, Leicester.

March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.

March 9 to 12.—Worthing Camera Club. Entries close February 29. Sec., Edmund F. H. Crouch, 11, South Street, Worthing.

March 12 to 14.—Shropshire Camera Club. Entries close March 2. Sec., W. D. Haydon, The Schools, Shrewsbury.

March 16 to 19.—Cripplegate Photographic Society. Sec., J. G. Denyer, 15, Ostade Road, Brixton Hill, S.W.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between December 2 and 7:—

TELEMETERS.—No. 26,546. Improvements in telemeters. Otto Eppenstein, Jena, Germany.

DRY MOUNTANTS.—No. 26,592. Improvements in dry mountants for photographs and the like. Kodak, Ltd., and Simon Victor Haus Chancery Lane Station Chambers, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

PHOSPHATE SUBSTRATUM.—No. 993, 1907. This invention relates to an improved process for preparing paper for photographic purposes.

It is a well known fact that most kinds of paper contain large quantities of metallic particles or particles of other reducing substances, whereby such papers are rendered perfectly useless for the production of photographic silver emulsion paper, more especially, if emulsions, such for instance as emulsions for copying out purposes, containing a surplus of soluble salts of silver, come into consideration.

It will readily be understood that these reducing impurities are rendered harmless, if a protecting layer is placed between the paper and the emulsion, which protecting layer prevents the impurities of the paper and the soluble silver salts of the emulsion from re-acting on each other.

A perfect result can be obtained by coating the impure paper with a protecting layer which contains salt insoluble or hardly soluble in water and alcohol. These latter salts re-act upon the silver salts, diffusing from the emulsion into the paper film in such a manner that insoluble silver salts, remaining within the protecting layer, are formed.

A proper selection of the kind and the quantity of the compound distributed in the protecting layer prevents all the silver salt from getting to the paper and inversely no substance detrimentally affecting the quality of the emulsion can enter from the protecting layer into the emulsion.

In selecting the protecting layer it is further requisite that the latter should be cheaply provided in a sufficiently pure condition and have a pure white colour. In practice, the protecting layer is substituted for the white layer, for instance of baryta as usual for photographic emulsion papers, so that the paper provided with the protecting layer can be coated with the celloidin, aristo- or the like emulsion without any further operation.

With this object in view, for the purpose referred to, the neutral phosphates of the earths and alkaline earths and of zinc are useful in a high degree, and among these particularly the neutral phosphate of calcium is extremely suitable. At this stage it may be pointed out that tri- and di-phosphates of calcium

are suitable for the purpose intended, and amongst these is for an instance the calcium phosphoricum referred to in the "Pharmacopœia Britannica II."

The phosphate is mixed with a binding medium having sufficiently inactive or neutral and resisting properties and then applied to the raw paper as usual. Experiments have demonstrated that a perfect protection is obtained if, for instance, the coating contains about 40 grammes of the "calcium-phosphoricum" referred to for each square metre of the paper. The protecting layer may, of course, if desired, be mixed with additions, colouring matters, or the like, being inactive and promoting the durability of the finished emulsion paper. York Schwartz, 3, Eden Strasse, Hanover.

**CELLULOSE EMULSIONS.**—No. 26,503, 1906. Among the acid esters of cellulose, collodion cotton alone has attained considerable importance as a material for the manufacture of emulsions for photographic purposes.

Various attempts have been made to utilise also the acetic esters for this purpose. For instance, Valenta (Eder, Jahrbuch für Photographie, 1902, page 582) has made experiments with the compound described by Cross and Bevan as tetracetate, and has had some success, which, in his opinion, gives some hope that emulsion papers of very good quality may be produced by means of cellulose tetracetate.

According to the German Patent, No. 169,364, only a certain group among the various acetyl-derivatives is applicable for this purpose, the principal characteristics of this group being their solubility in alcohol.

I have found that all kinds of acetyl-cellulose, either singly or combined, may yield excellent emulsions, if they are dissolved in acetic acid. For this purpose pure acetic acid solution may be used, or acetic acid solution mixed with one or more other liquids. It is practicable even to use directly the mass obtained by the acetylation of cellulose, provided that the condensing medium contained in the same has been neutralised by the addition of suitable chemicals.

The following example will explain the details of procedure which may be employed for obtaining one of the new emulsions.

#### EXAMPLE:—

To 1,000 cubic centimetres of a  $2\frac{1}{2}$  per cent. solution of cellulose acetate in acetic acid are added 35 grammes of a mixture consisting of crystallised strontium chloride (45 parts), anhydrous lithium chloride (1.5 parts), water (9 parts), and absolute alcohol (20 parts); to the mixture thus produced are then added 25 grammes of glycerine which has been mixed with 25 grammes of absolute alcohol, after which a jet consisting of 30 grammes of silver nitrate dissolved in 40 grammes of water and 75 grammes of absolute alcohol is caused to run into the said mixture, while continuously shaking the latter. After the materials have been thoroughly shaken together, a solution of 10 grammes of citric acid in 40 grammes of absolute alcohol is added.

The emulsion thus obtained may be poured on a suitable base in the usual manner. Materials pervious to water are thereby rendered water-repellent, so that sheets of porous flexible material, such as paper, cotton, linen, and silk fabrics, become eminently suitable as bases or supports for the emulsion, and the sheets thus impregnated are suitable for photographic purposes.

If the emulsion is applied to a film, plate, or layer of cellulose acetate, an intimate fusion with the latter takes place. Dr. Leonhard Lederer, Manufacturing Chemist, Sulzbach, Oberpfalz, Germany.

The following complete specification is open to public inspection before acceptance, under the Patents Act, 1901:—

**CINEMATOGRAPHS.**—No. 26,107. Cinematographs. Dupuis.

### New Trade Names:

**ALPHA.**—No. 297,612. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives.

Colthurst and Harding, Mansion House Chambers, 11, Queen Victoria Street, and Alpha Works, Millwall, London, and Phoenix Wharf and Temple gate Bristol; white lead, paint, colour, and varnish manufacturers, oil boilers and refiners. November 1, 1907.

**C. URBAN (signature).**—No. 297,639. Cinematographic apparatus and photographic films bearing finished pictures for use therewith. Charles Urban, 48, Rupert Street, London. November 1, 1907.

**GUMMITE.**—No. 297,398. Photographic trays, basins, tanks, and similar goods, not included in other classes, all being made of material covered by Class 50. Compagnie Générale d'Electricité, 5, Rue Boudreau, Paris, France, manufacturers. October 24, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### An Idea for Christmas.

The following are a few instructions (writes Mr. R. J. Sutton in "Focus") to make a snow scene of any negative, providing it has not a mass of detail, which would render it a rather hard task. It is done very simply by painting on the glass side of the negative, with opaque watercolour, the parts to be obliterated temporarily, and printed in the shade, so as to produce a soft effect. Churches, cottages, etc., form very suitable subjects, and make very pretty Christmas cards. A motto can be printed simultaneously in the same manner, and gilded or coloured after the card is dry. The effect is in a good many instances very much enhanced by printing a black border round the card, which is done by placing the card, after the subject is printed, in a printing-frame, with a sheet of plain glass, and the centre masked off by black paper cut a little smaller than postcard size, and the edge exposed allowed to print as dark as is required.

### The Drying of Oil Prints.

There has been heard occasionally an outcry against the oil print not drying (writes Mr. John H. Gear in the first of a series of articles in the "Amateur Photographer"), and the difficulty in handling the print. It must be borne in mind that an oil painting is not a thing to handle for some hours after it has been painted; as a matter of fact, decorative work in general, of which oil colours play a part, is given a reasonable time to dry hard. A photographic oil pigment print must be likewise given a reasonable time to dry. If quick-drying ink is used, it will not impart the rich luminosity of the shadows, a feature in which the process surpasses all others without appearing garish. But a print should be sufficiently dry to handle with care in mounting and framing within about forty-eight hours after production, unless it has been abnormally pigmented. Personally, I much prefer a print to take several days to sufficiently harden to allow of handling; with such, the effect is generally better. It may not, however, be the consistency or constituents of the pigment which influence rapid or prolonged drying; it may be entirely dependent upon the paper used. Ink may be used upon a given sample of paper, and the print will dry in twenty-four hours. The same ink upon another paper will not dry to an equal extent in two or three months. Therefore it is of the greatest importance that a suitable paper is selected, especially by those who have not thoroughly mastered all the vagaries to which the process is subject; and one of the best-working papers in my hands is the Double-Transfer No. 76 of the Auto-type Company, which has a sufficiently thick film of gelatine to admit of all the latitude desired in pigmenting, yet not so thick as to destroy the surface texture of the paper.

**LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.**—The annual exhibition of this society will be held from February 19 to 21, 1908, the latest date for entries being February 8. Further particulars may be obtained from the Secretary, Mr. T. Mottershead, 32, Stafford Street, Longton.

## New Books.

"The Burlington Art Miniatures," Part IV. The Fine Arts Publishing Company, Limited, London, E.C.

Part IV. of this fortnightly publication fully bears out the promise of Part I., reviewed in our issue of November 1. This new number contains Botticelli's "Madonna and Child," "The Broken Pitcher," by Greuze, Franz Hals' "The Gipsy," Millet's "The Gleaners," and other well-known pictures by Corot, Madam Lebrun, Da Vinci, Van Dyck, Holbein, etc. As we stated before, these mezzograph reproductions are well worth the cost of 1s. 6d. per number.

"Hazell's Annual" for 1908 is in no way behind its predecessors in the variety and scope of its information, which is thoroughly up-to-date and given in a form easy of reference, the book being compiled on the alphabetical system and also possessing a copious index. That it meets a need in the world of "Annuals" is evidenced by the fact that it has now attained its twenty-third year, and the Editor is to be congratulated on the way in which, year by year, he anticipates the wants of the busy man by summarising important events in such a manner that the necessary information is given in the smallest possible space without any unnecessary embellishments, and it is doubtless an appreciation of this fact that has made "Hazell's" one of the most popular annuals of the present day. The book, which is strongly bound in red cloth and published at 3s. 6d. net, may be obtained from the proprietors, Hazell, Watson, and Viney, Limited 52, Long Acre, W.C., or from Hodder and Stoughton, Warwick Square, E.C.

## New Materials.

Faverno Mounting Boards. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

The above firm submit samples of some new mounts prepared with fine linen surface and in an excellent series of colours. The tints are whites, browns, and greys, and, though limited in number, they are all good and of just the shades that are most commonly useful. The thicknesses are 3, 6, and 10 sheet, and the respective prices are 18s. 6d., 29s. 6d., and 40s. 6d. per gross for royal size, and 24s. 6d., 39s., and 54s. per gross for imperial size. Embossed mounts for midget, C.D.V., and cabinet are also supplied in the same boards with circular, oval, or square designs, at prices varying from 4s. to 9s. 6d. per hundred. The designs in the samples submitted to us are quite simple, and free from the unnecessary elaboration that makes many varieties of embossed mounts so objectionable. The shapes are also good, and the appearance of the whole series very satisfactory.

Passepartout Frames and Mounts. Lawrence and Aitken, Albion Works, Kilburn, London, N.W.

Messrs. Lawrence and Aitken have introduced a new line in passepartout mounts at very moderate prices. These are very complete, and include glass, cut tinted mount, back with rings attached, and a back strut that can be attached if desired. The adhesive binding strips are already attached to a front card frame, therefore in use it is only necessary to lay down the glass, mount, photograph, and backing board in due order, upon this frame, and to turn the moistened binder down over the back. The glasses and the back struts can be provided or not as the purchaser may wish, corresponding variations in the price being of course made. With mounts such as these all the difficulties of securing a uniform width of frame and of producing neat angle-joints disappear. There are, in fact, no angle-joints, as all four side-binders are in a single piece of material, and the rectangular piece cut out to form the opening is utilised as the backing board. This ingenious method of manufacture greatly simplifies the operation of mounting, and renders a neat finish almost

automatically attainable. We are glad to see that the rings are strongly and properly attached to the backs, this being a weak point with some varieties of passepartout framing.

VICTORIA POSTCARD MOUNTS.—Messrs. Houghtons Ltd. introduce a new series of embossed mounts of postcard size, arranged to take quarter-plate prints, and printed on back with "Postcard" and the usual postal instructions. Mounted prints can now be sent through the post at postcard rates, and these mounts have been designed to

conform with the postal regulations. They are sold in packets of sixteen at the moderate price of 6d., and two series are issued. Series 1 is in browns and warm tones suitable for toned prints, and Series 2 in slates and greys suited to platinotypes and black and white processes generally. The designs are simple and effective, and the colours good, hence these mounts should become popular.

## CATALOGUES AND TRADE NOTICES.

THE City Sale and Exchange, of Aldersgate Street, Fleet Street, Lime Street, and King's Road, Sloane Square, send us price-lists of optical lanterns, cinematographs, and accessories, and a very complete list of lantern slides, that fills 336 pages of small type. All slides are for either sale or hire, and the Sale and Exchange make a special feature of their subscription lantern-slide library.

FROM Mr. Jonathan Fallowfield we receive an illustrated price-list of Christmas and New Year mounts. This shows a very large variety of mounts of all shapes, sizes, and tints, listed at prices from 6d. up to 10s. per dozen. It would appear to be difficult not to find a suitable mount in such a comprehensive list as this, and those proposing to use photographic Christmas cards should send for this list without delay.

CRITERION SPECIALTIES.—The popularity of the well-known "Criterion" papers may be estimated by the fact that in the latest price-list issued by the Birmingham Photographic Company they state that owing to the increased demand for these papers they have been compelled to discontinue the manufacture of accessories, with the exception of a few which are in constant request. The list contains full particulars of the papers, postcards, and accessories manufactured by the firm, and may be had post free on application to the Birmingham Photographic Company, Limited, Criterion Works, Stechford, Birmingham.

THE TELLER CAMERA Co. are issuing a catalogue of second-hand and shop-soiled photographic goods at considerably reduced prices. The list, which extends to forty-eight pages, includes practically all makes and types of cameras, hand and stand, a large selection of lenses by well-known makers, enlargers, lecture lanterns, tripods, shutters, changing boxes, and a number of sundries too numerous to mention. The list may be obtained by any of our readers on application to the above firm at 68, High Holborn, London, W.C.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, DECEMBER 10.

Aberdeen Photographic Association. "Autochrome Colour Plates." Forbes S. Brown.  
West London Photographic Association. "Still Life by Artificial Light." F. C. Hart.

SATURDAY, DECEMBER 21.

Aberdeen Photo Art Club. "Bird Photography." Thos. Tait.

MONDAY, DECEMBER 23.

Catford and Forest Hill Photographic Society. "The Theory and Practice of Tim. Development." W. F. Slater, F.R.P.S.  
Graysend and District Photographic Society. Social Evening arranged by Messrs. Hurst & Winnett.  
Ridgeway Photographic Society. "Development." Wm. Hume.  
Kidlington and District Photographic Society. Competition, "Christmas Cards."

TUESDAY, DECEMBER 24

Royal Photographic Society. No Meeting.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 17, Mr. E. J. Wall in the chair. A paper by Dr. C. E. K. Mees and S. H. Whitten on "Plates sensitised with dicyanin and the Photography of the Infra-red," was read by Dr. Mees. The author described the remarkable sensitising properties of dicyanin, and instanced the particular cases in which it would be of service; its maximum of sensitiveness lay about 7,100, and there was a large gap between the blue and red. Plates bathed with the dye were particularly useful in photographing spectra where considerable resolution was required near to  $\alpha$ . In making spectra of sunspots and in other photography of solar phenomena the special properties of dicyanin had been found of service. The authors had also noticed the excellent rendering of clouds in a blue sky given by the dicyanin plates.

A short discussion, in which Messrs. C. P. Eutler, F. F. Renwick, and Oliver Dawson took part, followed the reading of the paper.

STAINES PHOTOGRAPHIC SOCIETY.—A very interesting demonstration was given at the Society's meeting on Tuesday evening, the 10th inst., by Mr. Green, a representative of Messrs. J. J. Griffin and Sons, Ltd., of Kingsway, London.

The subjects dealt with by the lecturer were "The Theory and Practice of Self-toning Papers," and "The Oil Pigment Process."

The lecturer fully explained the chemical properties of self-toning papers and the chemical reactions which take place during the process of toning.

Messrs. Griffin have recently placed on the market a new self-toning paper called "Goldona," samples of which were given away to those present. Prints on various grades of "Goldona" paper were handed round for inspection, the excellency of which was much commented on by the audience. Untoned prints were also toned and fixed, all of them with excellent results. The chief advantage of this paper is that no gold toning bath is required, the gold being in the paper itself, the toning and fixing being done by immersing the print in hypo solution until the required tone is obtained. The tone may also be varied by altering the strength of the hypo bath. A print was also shown, half of which had been exposed to the sunlight in a window for six months without any apparent deterioration.

The lecturer afterwards described Rawlins' oil pigment process. A print is made by daylight on a piece of paper coated with gelatine, sensitised in a 5 per cent. bichromate solution. The printing is allowed to continue to about the same depth as platinotype printing and the print is then washed in water for half-an-hour until all trace of the image has disappeared. The gelatine surface then possesses this peculiar property: that it has absorbed more water where the action of the light has been retarded by the density of the negative than in the thinner parts where the light has had more

effect. The pigment is then applied by means of a brush, and it will be found to attach itself more readily where the water has not fully acted on the gelatine surface, thus producing a picture. This process is very artistic, and allows the operator to exercise local control in printing to almost any extent. A print was washed and pigmented before the audience, the process appearing delightfully simple and fascinating, after which the proceedings closed with the usual vote of thanks.

SOUTHAMPTON CAMERA CLUB.—Mr. C. H. Hewitt, of Polytechnic fame, lectured to the members of the above on Monday evening, his subject being "A Chapter of English Architecture." The period chosen by Mr. Hewitt was that of Early English, and it was treated in the most exhaustive manner. The lecturer pointed out first the chief characteristics of the Norman work, showing how the Normans failed to build scientifically, though their work was so massive, and contrasting therewith the lighter Gothic work. The chief work carried out in the reign of Richard I.—that at Lincoln, Winchester, St. Albans, and Ely; in John's reign at Worcester, Fountains and Beaulieu; and under Henry III. at Salisbury, Wells, Durham, Ely, Peterboro', and Lincoln—were all referred to, and it was shown how the period was merged into the Decorated and Perpendicular. Going into detail, and illustrating by means of some very fine slides, Mr. Hewitt pointed out the chief characteristics of the Early English work. Outside the buildings he showed the lancet windows with their dripstones, the string course, and the corbel table, and explained the introduction of the flying buttress. Inside the buildings attention was called to the groining of the inner roofs, with its plain and ornamented rib work and carved bosses, then to the mouldings of the arches, with their dog-tooth carvings, the stiff foliage capitals, and the clustered pillars, with their bands and capitals. The lecturer then treated the doorways, showing Early English additions and insertions to the Norman work, and passed on to the arcading, showing by fine slides the double arcading at Lincoln and Beverley Minster. Finally came the crocket work, with its transition into the decorated stage, no single detail of the Early English style being left undemonstrated. Mr. Hewitt received a very hearty vote of thanks.

WOOLWICH PHOTOGRAPHIC SOCIETY.—On the 12th inst. Mr. H. W. Bennett gave a demonstration on his original method of toning bromide prints, with hints as to mounting, etc. This method, in which the results bear a strong resemblance to carbon prints, has the advantage of being cheaper and quicker to produce than carbon work, though it is not quite so permanent, and will doubtless appeal to many who have not the spare time necessary for the production of good results in carbon.

EPSOM AND DISTRICT LITERARY AND SCIENTIFIC SOCIETY.—Before a not very representative gathering of the photographic section of the above society last week, Mr. Peacock, of Croydon, gave a most instructive and successful demonstration on "Ozobrome." After a short description of the chemical action and the theory of carbon printing he proceeded to make Ozobromes from bromide prints provided by the members, and succeeded beyond all expectations. Under his direction several members made ozobromes for themselves, proving the simplicity of the process. Amongst the specimen prints Mr. Peacock showed some he had made with the new Ozobrome transparency tissue on unprepared glass by single transfer, which were of very fine quality. The meeting closed with a vote of thanks to Mr. Peacock, who undertook the demonstration at the eleventh hour, upon Mr. Stedman, of Messrs. Illingworth, failing through illness.

AN INTERESTING PRESENTATION.—A recent meeting of the Redditch District Council was marked by an unusual and pleasing event, when Mr. A. Harold Clarke, photographer, of Evesham Street, presented to the Council a large and handsomely framed group of portraits of the chairman and members, which now occupies a prominent position in the Council Chamber. This might well form the nucleus of an interesting and historical collection if all future members would, upon election, present a portrait of themselves to be hung beside the present group.

## Commercial & Legal Intelligence.

**CHARGE OF EMBEZZLEMENT.**—Arthur Ernest Wagner, 19, a photographer, of Drayton Road, Leytonstone, was charged at Stratford Police Court last week with embezzling various sums of money amounting to £4 10s. 6d., received by him on account of his employer, John Douglas; further, with stealing a camera, lens, case, and three slides, valued at £3, the property of Mr. Douglas.

The prisoner was in the employment of Mr. Douglas, photographer, of High Road, Leytonstone, at a weekly salary of 25s., and in the course of his duty he received moneys which he was supposed to account for to Miss Lilian Hine, the manageress. On November 2nd he received £2 from the Rev. E. W. Sawyer, of Leytonstone, but he did not account for it. Inquiries showed that he had accounted for other sums.

An examination of the stock showed that a camera was missing, and the prisoner, when charged with the theft, made no reply. The camera he had sold for a sovereign to a lad named Isaacs, who was also an assistant to Mr. Douglas. The Bench were of the opinion that it was a very bad case, and sent the prisoner to gaol for six weeks' hard labour for the embezzlement. The larceny was not dealt with.

**WHAT IS A SUMMER-HOUSE?**—On Monday the Hove magistrates gave a decision which has special interest for gardeners, photographers, and others who construct places of retreat or shelter in private grounds. Mr. Samuel Henry Perrin, a solicitor, has become a resident in Hartington Villas, in the back garden of which he had erected a corrugated iron shed, 12 ft. by 18 ft. by 6 ft. The local surveyor inspected the shed, which contained three bicycles, chairs, and other articles, and he summoned Mr. Perrin for failing to notify the authorities of the construction of the shed as required by the regulations.

One of the points raised by Mr. Perrin in his defence was that the building being in the nature of a summer-house, was exempt from the by-law, and in support of his argument he instanced cases where disused railway carriages and tramcars were utilised for garden purposes without coming within the scope of the regulations.

The surveyor denied that the shed was a summer-house.

Defendant thereupon quoted definitions of the term summer-house from Walker's and Nuttall's dictionaries, laying particular stress upon the description in an encyclopædia, 1901, of "a house, building, or shed in gardens for use in summer."

The magistrates were of opinion that the building in question did not come within the meaning of the by-law, and the summons was therefore dismissed.

Mr. Gell-Woolley, on behalf of the Corporation of Hove, asked the magistrates to state a case, with the view to an appeal, and this was agreed to.

**BRITISH PHOTO PAPER COMPANY, LTD. (Lambeth).**—Issue on November 27 of £250 6 per cent. debentures, part of series created November 6, 1907, to secure £5,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £1,800.

**CAMPBELL-GRAY, LTD. (Photographers, London).**—Issue on November 27 of £250 6 per cent. debentures, part of series created November 7, 1907, to secure £1,000, charged on the company's undertaking and property, including uncalled capital. No trustees. Total amount previously issued of same series, £350.

**CAMERA THEFTS.**—Morris Meyer Cohen, 49, a general dealer, living in St. George's Road, Southwark, was charged at Marlborough Street last week with the theft of a pair of binocular glasses, worth £6 10s., from James Sinclair and Co., opticians, Haymarket; also with stealing a camera, valued at £8 8s., the property of the Stereoscopic Company, Ltd., Regent Street. The articles in question were missed a few days ago from the shops of the prosecutors, and while Detective-sergeants Clarke and Burton were in Bedford Street they saw the prisoner there with the missing camera. When the officers approached him he ran away, but was

eventually captured, and said that he had stolen the articles from the shops mentioned, and also twenty sixpenny diaries from the premises of Messrs. Boots, in Southwark Street.

Sergeant Clarke informed the magistrate that another prosecutor who had lost valuable bronzes was present, and the prisoner answered the description of a man "wanted" for a number of thefts of cameras which had been disappearing of late all over London.

The accused was remanded.

### NEW COMPANIES.

**SERIKON, LTD.**—Registered November 27.—Capital £7,000, in £1 shares. Objects: To acquire the business carried on by Birt Acres at Whetstone as the Whetstone Photographic Works, and to carry on the business of manufacturers of and dealers in celluloid, cinematograph and photographic films, plates, chemicals, and apparatus, photographers, opticians, etc. No initial public issue. Registered office, Whetstone Photographic Works, Whetstone, Middlesex.

## News and Notes.

**THE HOME OF THE AEROGRAPH.**—It is very probable that a large proportion of the many workers in all parts of the globe who are users of the "Aerograph" are unaware of the modern developments of this instrument. Even the passer-by along Holborn Viaduct may scarcely notice in the window of the Aerograph Co.'s premises the examples of air-brush work along lines which have virtually created a new industry. The "Aerograph," as everybody knows, was invented by Mr. A. L. Burdick in the first instance as a time-saving tool for artists, a tool, too, which allows its possessor to obtain effects he could not reach by hand. It is fifteen years since photographers in this country first had the Aerograph offered to them, and few at that time anticipated that the firm exporting it would soon be showing its wares in as handsome a showroom as any in the City of London, and be occupying a four-story factory within the City itself for the manufacture of the instruments. We will confess it was with some surprise that we recently found at Mr. Burdick's working establishment in St. Luke's, E.C., no less than seventy-five workpeople, chiefly mechanics, engaged in the manufacture of air brushes of various types. In 1895 the staff consisted of two workmen and a boy, and the back streets of Clerkenwell were ransacked for artificers capable of carrying out certain of the delicate work in the production of the instruments. Now the company has its own machinery and tools, and is fully equipped for exercising its own supervision over the manufacture of every working part of the product. This state of things is no doubt the result of Mr. Burdick having himself worked out the actual making of Aerograph parts at a time when he could not get the necessary accuracy elsewhere. We were interested in witnessing the adjustment of the German silver stylus of the Aerograph to the platinum nipple, and the nicety of fitting which is necessary for (1) the proper flow of colour and (2) the ability to draw a fine line. In other respects the Aerograph has undergone great developments since its inception: it has its working parts enclosed, it is readily cleaned and recharged with a different colour, and it has proven itself capable of withstanding constant working usage year in year out, much as a well-made camera may get somewhat out of date, but does not wear out. That such facts may be put down to the credit of the Aerograph is not surprising when the facilities of the maker's factory are inspected.

Yet the quite recent developments of Aerography are even more surprising than the perfection to which the photographer's special instrument has been brought. The use of the air-brush through a stencil has shown itself capable of great industrial applications, and we saw last week the first completed rotary Aerograph machine, designed and built by Mr. Burdick for the automatic decoration of fabrics, wallpapers, and the most diverse materials. Several colours are simultaneously applied, and patterns of any required intricacy dealt with. Many photographers who pride themselves on their technical knowledge very likely do not suspect the air-

brush as the active agent in the ornamentation of the voile or mousseline de soie which forms parts of the toilette of their women-folk. Yet these and many other articles of commerce owe their adornment to the machine-aerograph which has proved itself a serious competitor with other methods of applying colour.

**SPIRIT PHOTOGRAPHY.**—Mr. A. J. Butler writes as follows in the "Westminster Gazette":—"May I refer any of your readers who are interested in this subject to a book by Miss Georgiana Houghton which appeared in the year 1882, entitled "Chronicles of the Photographs of Spiritual Beings and Phenomena Invisible to the Material Eye" (E. W. Allen)? They will, I think, find it instructive. I need not take up your space with a detailed account of it, but I may say that a study of the specimens of the art which are given in it shows clearly that the same young lady, and a good-looking one at that, did duty for such diverse spirits as those of "Manoah's wife," "Mrs. Ramsay's daughter," "the sister of George Sutherland, Esq.," as well as a number of less precisely identified visitors from another world. There is also a male figure—less prepossessing—who appears sometimes with, sometimes without, a beard, but perfectly recognisable in either guise. I do not know, not having given much further attention to the subject, how far the art of "spirit-photography" has progressed in the last quarter of a century, but it seems from the letters in your columns, that the scientific training of its devotees remains much where it was.

**PHOTOTELEGRAPHY.**—The Berlin correspondent of the "Daily Mail" states that it is announced that the first regular station for the transmission of photographs by telegraph will be established at Munich on December 15. A similar station is to be established in Berlin, London and Paris will later be connected with a service, so that the first commercial exchange of pictures by wire will shortly be inaugurated between these four cities.

**THE NEW EGYPTIAN HALL.**—Sir William Treloar, Bart., on December 11, opened the New Egyptian Hall, which is to be devoted to the display of high-class cinematograph pictures. He said he was sure the entente cordiale would not be diminished by the support which the English people were sure to give to the entertainment carried out mainly by Messrs. Pathé. Mr. A. E. Simonsen, on behalf of the management, thanked Sir William for his presence, and asked him to fix a day on which he would send his cripples there to enjoy the entertainment.

**LANTERN SLIDES OF HOLLAND.**—Messrs. A. E. Staley and Co., who, in August last, held an exhibition of Mr. Stanley E. Fincham's photographs of Dutch scenery, now announce that they are preparing a collection of 150 lantern slides made from negatives also taken by Mr. Fincham during his recent visit to Holland. These slides, which will be ready by January 1, 1908, Messrs Staley will be pleased to lend to any photographic society desirous of giving its members an interesting and instructive lantern evening. Mr. Fincham has also written a lecture to accompany the slides giving details and description of the various places, etc., represented in the tour. Those secretaries who wish to avail themselves of Messrs. Staley's offer should make early application, with dates, to the above firm at 19, Tavies Inn, Holborn Circus, London, E.C.

**TRADE ENLARGING AND PRINTING.**—Mr. E. P. Grigg notifies us that he has opened new premises at 29, Neal Street, West Bromwich, where he will in future carry on his business of enlarging, printing, etc. Whilst undertaking all descriptions of photographic work, Mr. Grigg makes a specialty of enlargements, which from an inspection of samples submitted, appear to us excellent in quality and reasonable in price. Those desirous of availing themselves of Mr. Grigg's services may obtain a copy of his trade price list on applying to the above address.

**PHOTOGRAPHY OF PAINTINGS.**—On Thursday, December 12, at the L.C.C. School of Photo-Engraving and Lithography, Mr. Donald Cameron-Swan, Managing Director of the Swan Electric Engraving Co., lectured concerning the photography of paintings, showing in illustration of his remarks a very large number of reproductions of works by artists of world-wide eminence, negatives, positives, and prints. The latter were mainly photogravure proofs, many being

signed by the artists. These exhibits being of such exceptional interest, they are by request remaining on the walls for inspection until Wednesday next, at the L.C.C. School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C. Admission is free between the hours of 10 a.m. and 5 p.m.

**"ABEL'S PHOTOGRAPHIC WEEKLY."**—A week or two ago we recorded the purchase of the "Photographer" (New York), edited by Mr. J. C. Abel, and its amalgamation with the "Bulletin of Photography" (Philadelphia). This latter journal has therefore for the past few weeks been the only photographic weekly in America, a distinction of which it is to be deprived by the issue by Mr. Abel of a journal under the title "Abel's Photographic Weekly." Events seem to take place quickly in the American journalistic world, and we hope that both active competitors will meet with precisely the reward in prestige and hard cash which they merit.

**SOUTH MANCHESTER PHOTOGRAPHIC SOCIETY.**—The seventh annual exhibition will be held in the Public Hall, West Didsbury, from February 20 to 22, 1908, inclusive. Mr. A. A. Bellingham and Dr. T. G. Crump have consented to act as judges, and fourteen specially designed bronze plaques will be placed at their disposal for award. There will be three classes open to all, four for members only, and one (Class 4) open to members of societies federated to the Lancashire and Cheshire Union, in which the "Amateur Photographer" special silver medal will be given to the best picture. The "Photographic News" silver medal will be awarded to the best picture shown by a member of the society. Entries close February 8, 1908, and entry forms, which are now ready, may be obtained from the Hon. Sec., Mr. M. W. Thompson, 22, Albert Street, Manchester.

**ILKESTON ARTS CLUB.**—The photographic section of this club will hold its fifth annual exhibition in the Town Hall, Ilkeston, from March 4 to 7, 1908. Mr. Arthur Marshall, A.R.I.B.A., will undertake the office of judge. The Secretary is Mr. Arthur Smith, 11, Graham Street, Ilkeston, from whom further particulars may be obtained.

**MESSRS. W. BUTCHER AND SONS, LTD.,** notify us that their telephone number is now 5995 Holborn (three lines), and their telegraphic address, "England, London."

**MESSRS. ELLIOTT AND SONS, LTD.,** ask us to notify that their factory, warehouse, and offices, will be closed from Tuesday night, December 24, until the following Monday, the 30th inst.

**CHRISTMAS HOLIDAYS.**—Mr. S. H. Fry, of Frisian House, Highbury Grove, N., intimates that his business premises will be closed from Tuesday, December 24, to Monday, December 30.

**ARTIFICIAL LIGHT PORTRAITURE.**—In reference to the recent letter from a correspondent, a reader of the "Journal," Mr. W. Carter, of 167, Old Kent Road, London, S.E., in sending us a large number of excellent commercial midget photographs, writes:—"I have taken this opportunity of forwarding for your opinion of same a batch of bromide prints from negatives taken by seven ordinary Bray burners, with tissue paper in front to diffuse light. The exposure is not ten but two seconds on 'Royal Standard' E.R. plates with Dallmeyer's 2B lens with full opening. In no case are the negatives retouched."

**PHOTOGRAPHING FANCY DRESS BALLS.**—The Baths Committee of St. Pancras Borough Council reported on Tuesday having received an application from Mr. L. Francis, 243, Kentish Town Road, N.W., for permission to take photographs at the baths on the occasion of fancy dress balls. He is prepared to provide his own apparatus, and will only require a supply of electric current. He is willing to pay for the privilege 5s. on the occasion of cinderellas and 7s. 6d. when long night dances take place. The Committee having ascertained that the proposal would not involve any alteration in the existing electrical fittings, acceded to the application.

**JUVENILE LECTURES AT THE SOCIETY OF ARTS.**—Mr. F. Martin Duncan will deliver two lectures, suitable for juvenile audiences, at the Society of Arts on Wednesday afternoons, January 1 and 8, at five o'clock, taking for his subject "The Scientific Applications

of the Cinematograph." Though at first sight the title may convey an idea of matters rather above the comprehension of the "juvenile" mind, yet those who have heard Mr. Duncan lecture, and who have read his books on Nature subjects, will fully realise that his peculiarly happy methods of imparting information render him particularly suitable for such a position as he now proposes to occupy, and those juvenile hearers who will doubtless throng the Society's rooms on January 1 will not be satisfied unless they are again amongst Mr. Duncan's audience on January 8.

**MARBLE ARCH IMPROVEMENT.**—The scheme suggested by Mr F. W. Speaight came before the Paddington Borough Council on Tuesday last, when the Works Committee recommended the Council to contribute £2,112, or one-ninth of the estimated cost (£19,000) of forming a crescent carriageway, 85ft. wide, minimum, at the rear of the Marble Arch, and thus isolating the arch. Alderman R. F. Whur, chairman of the Works Committee, in moving the adoption of the recommendation, stated that the London County Council had agreed to pay two-thirds of the cost of this improvement if Westminster, Marylebone, and Paddington gave the rest in equal proportions. The First Commissioner of Works had consented to concede a portion of Hyde Park for the purposes of the widening. Paddington, he contended, would most largely benefit by the improvement, although only a few square yards of the ground were within the limits of the borough. After some discussion, the recommendation of the Committee was adopted.

**GAZETTE NOTICES.**—Notice is given in Tuesday night's "London Gazette" that Harry Chapman Whiteley and Ernest Crossley, carrying on business under the name of the "Novelty Animated Picture Co.," in Huddersfield, as cinematograph and lantern entertainers, have been adjudicated bankrupts. Notice is given of the release of the trustees of Arthur Henry S. Draycott and John Arthur Draycott, trading under the name of the "Draycott Galleries" as photographers and dealers in works of art, at Leamington and New Street, Birmingham. The case was before the Birmingham Court in 1906.

### PINHOLE APERTURE NUMBERS.

To the Editors.

Gentlemen,—In the table of Watkins-Power pinhole numbers, page 944, BRITISH JOURNAL ALMANAC, just published, the editorial footnote states that the system is due to Dr. D'Arcy Power. The fact is that it is a modification (and a very happy one) made by Dr. Power on a system originated by me. I devised the plan to name the pinhole aperture as if it were sixty times its real area, so that a calculation made in seconds will be correct if given in minutes, and Dr. Power adopted this plan. For example, here is one line from my original table of about ten years ago:—

No. of Needle (as packet).	Diameter.	Diaphragm value.	Working distance.
5	$\frac{3}{16}$ inch	$\frac{1}{10}$	15 inches.

Here I gave the diaphragm value for the working distance of 15 inches only. Dr. Power gives it for one inch, and so enables it to be multiplied by any working distance. As a matter of fact, the Power numbers can be found from my original table by dividing the diaphragm value by the working distance. In the above example, for instance, the Power number is 4 (being  $\frac{4}{10}$ ), and it will be seen from the footnote I refer to that a pinhole of  $\frac{3}{16}$  inch diameter is called No. 4 by Dr. Power. I do not count my later modification of making

an allowance of 50 per cent. for the "law of error" as entitling me to give my name to the system in conjunction with that of Dr. Power. It is the basic idea of dividing the aperture by  $\sqrt{60}$  in order to name it—which method had been published and practised for years before Dr. Power's modification—which entitles me to a full half-share of credit in the Power or Watkins-Power method.—Yours truly,

ALFRED WATKINS.

Hereford, December 14, 1907.

### PORTRAITURE WITH THE MERCURY VAPOUR LAMP.

To the Editors

Gentlemen,—I have read Mr. Henderson's letter in your issue of the 13th, and although he says at the end that he cannot enter into any further discussion on the matter, I think it is only fair to myself to shortly reply to his remarks. Because some provincial firm of photographers could not start their eight arc lamps when they wanted to show them to Mr. Henderson, he commits himself to the statement that "an extraordinary amount of practice and skill," and "enormous amount of patience," an "unlimited amount of energy and zeal," and a few other adjectives are required to work photographic arc lamps; also "the uncertainty of the electric arc lamps," "the difficulty in starting the lamps, the flickering and unsteadiness of the light, and other minor faults which seem inseparable from the arc lamp," as sufficient reason to account for the shyness which photographers show in adopting this form of lighting for the studio." Sufficient reason, indeed, if such troubles existed anywhere out of Mr. Henderson's imagination. My firm have supplied a large number of photo. arc lamps during the last nine years which possess none of these characteristics. This is also some answer to the "shyness" which I am only too pleased to say does not exist, as we find the demand for such lamps rapidly increasing. We receive many testimonials from photographers remarking on the extreme simplicity and ease of working, and the excellence of the results obtained. The originals of these are quite at your service.

By the way, what did Mr. Henderson's provincial photographer want eight arc lamps for? One or two are sufficient for most studios. Of course, the arc lamp gives heat, but there is no need to put the frames so near to the lamp as to cause any trouble. The printing is quite rapid enough at a safe distance. A "Westminster" No. 114 lamp on a 200 volt circuit takes 15 amperes, which is three units per hour, and not seven, as Mr. Henderson says, which, of course, knocks the bottom out of his statement as to comparative economy.

In looking through Mr. Henderson's article again (November 22nd issue), under the heading "Installing the Lamps," there are some remarks about wiring, which I will quote. "Another point which is of great consequence is the main wiring, which should be what is known as 22 wire. This should have a distance of not less than two inches between positive and negative wires. This is necessary to prevent induction. It is only necessary to have this space left from the switch to the lamps." Now this is simply nonsense, and brings me to the reason for my intervention in this matter at all, as I am an electrical engineer and not a photographer. Mr. Henderson has had some mercury vapour lamps, and has used them for twelve months with results that are satisfactory to himself. He is therefore perfectly justified, and indeed, much to be commended for giving an account of his experience, but why! oh why! does he consider it necessary to attack and condemn other systems, and give instruction about other matters which are evidently outside his knowledge? Let him stick to his mercury-vapour lamps, and I am sure all your readers will be pleased to read whatever he has to tell us about them as the result of his own experience.

I am sorry if I have said anything to hurt his feelings, but I should expect to be pitched into in much the same way if I wrote an article on arc lamps and condemned everything else, including mercury-vapour lamps (which are, no doubt, excellent lamps, and will take portraits if you wait long enough, or use a sufficient number of them) without first making sure of my facts.—Yours faithfully,

J. O. GIRDLESTONE.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPH REGISTERED:—

E. A. Basevi, 26, Tenison Road, Cambridge. Photograph of the Rev. R. H. Benson, M.A.

**THE PEDLARS ACT.**—A few days ago I was walking along the road, with my camera slung over my shoulder and a few samples of my work with me. I met a police constable and his sergeant, who stopped me, and, after looking at the samples, said I was hawking and required a pedlar's licence. I argued with them for some time, telling them that I was not selling anything, but canvassing orders, whereupon the sergeant said he warned me not to do it, passing some remark about my selling my skill and handicraft and obtaining orders for same, and if he saw me again he would apprehend me. Do you think he is right, or is there some mistake? This is the first time I have been stopped. Sometimes I go out with my handbag containing samples and obtain orders from houses for postcards, etc., and at present Christmas cards (photographic ones). I also carry samples of views, from which stationers give their orders. On another day I may go out with my camera to photograph houses or persons from whom I had obtained an order. On this particular day, when stopped, I had both camera and samples. I should like to know, through your valuable journal, if I am doing wrong and if a licence is absolutely necessary. There must be hundreds of other photographers who earn their living in this manner. I may say that I do not go about from one town to another doing this, but have a place of business in this town.—ANDCO.

The police-sergeant is quite right. Your method of doing your trade certainly brings you within the Pedlars Act, and you require a licence. As you have been cautioned by the police, you will do well to get it at once, or you may find yourself in trouble. The licence costs 5s. a year—not a large sum.

**PRINTING BY ARTIFICIAL LIGHT.**—I wish to know, through the medium of your paper, if I could get a lamp with which I could print P.O.P.—something like Houghtons' Jandus arc lamp, but which would not require electric power. I am in a large village, and am without the advantage of having either gas or electric light, and as I do a large amount of P.O.P. postcards and larger work, a lamp such as the above would be a great boon to me.—W. M. JONES.

There is no such lamp made. What we would suggest is that you partially print by daylight and then develop the prints in the usual way—that is, if you must use P.O.P. On p. 819 of the "Almanac" for 1908 are formulæ suitable for the work.

**BLOCKING-OUT SKIES, ETC.**—1. I have some negatives marked in red ink, and would feel greatly obliged by you telling me of anything which would remove this? The marking is on the film, and I doubt if anything will remove it. 2. I got in your paper some time ago directions for making defective skies dense without actually blocking-out in Indian ink. The negative was to be varnished with collodion and then worked over with elect. plumbago, then (as I read it) to be varnished a second time

with seedlac, sandarach, oil of lavender, castor oil, and alcohol. This to be matted with powdered resin, and electrotypers' plumbago applied. I am not sure whether I am right in supposing this to be one process, or is it two different methods of blocking-out. 3. Also, please say what may be used to remove the coating if it should be necessary to do so.—RETOUCHER.

1. The composition of red ink varies with different makers, and without knowing that of the one used we cannot help you. 2. We do not call to mind the method referred to, and "some time ago" is too indefinite a date to enable us to search for it. However, if you coat the negative—back or front—with matt varnish you can work on that with the plumbago. 3. The matt varnish can be removed with methylated spirit.

**TRANSFERRING COLLODION FILM.**—I intend making a positive on a glass support by the wet-plate collodion process. Will you kindly tell me the best way to transfer it from the glass to a metal support as soon as it has been fixed and while still wet?—WET PLATE.

To do this successfully will require neat handling. First remove the film from the edges of the glass. Then put the plate in dilute hydrochloric acid—about one part to ten parts of water. In a few minutes the film will be loosened. The plate must then be carefully rinsed under the tap to remove the acid; it is then put into a dish of water, when the film may be floated off the glass on to the metal support. It will be well to employ a rather thick collodion—one with a good body.

**CARBON TISSUE.**—Will you kindly give formula and directions for making (on a small scale) carbon tissue for three-colour work—something with pigments that are practically permanent, if possible?—W. H. THOMPSON.

No very definite instructions are published on the manufacture of carbon tissue. The best, perhaps, are those given in Wall's book on the carbon process. We may tell you, however, that the making of carbon tissue on a small scale is by no means an easy matter to the novice, particularly for three-colour work. We should advise you to purchase the tissues, specially made up for the work, as supplied here by the Rotary Photographic Company or the Autotype Company.

**SALARY.**—A late employer owes me salary amounting to £10, and in reply to my requests for payment says he has not forgotten me, but cannot pay me yet. I know he will shortly become bankrupt, and I would like to know if I (a past employee) would be classed as an ordinary creditor and receive the same percentage of payment, or should I get full payment for my services. Thanking you in anticipation.—HILDA.

If you were an employee at the time of the bankruptcy you could, if a weekly servant, claim a month's salary in full. But we are not sure how you now stand, as the late employer is not yet a bankrupt. We would think your best procedure will be to take out a summons at once in the county court for the sum due, so that you will stand as a preference creditor for your salary.

**POSITIVES ON CELLULOID.**—At a holiday resort here I saw a machine taking direct positive pictures on celluloid, and shall be glad if you can give me any information as to how this is done. The machine was operated somewhat as follows: A gelatine emulsion is coated on celluloid, exposed, then developed, apparently, I believe, in hydroquinone; then the negative image reversed with a second solution, and fixed by a third, the whole operation taking about fifty seconds before the picture was delivered. In order to facilitate the drying, a few drops of alcohol were sprinkled on it, so that the moisture would evaporate quickly. It is a good many miles to write for such information, but I feel sure that you are in a position to give me some suggestion as to how this is done, as I should very much like to make some experiments to produce some of the pictures. The results were very fine, looking just like an ivory miniature, and from questions asked I learned that they were developed with a very strong hydroquinone developer.—W. GREEN (New York).

Without seeing a specimen of the pictures we can give no decided opinion as to how they are done. We imagine, however, that the system is somewhat similar to that which is

employed for taking ferrotypes in the automatic machines, except that the emulsion is on celluloid instead of being on a ferrotype plate.

W. SCOTT.—"The Kinematograph and Lantern Weekly," published by E. P. Heron and Co., 9-11, Tottenham Street, Tottenham Court Road, W.

F. Q. WARNER.—Your idea seems a good one for practical workers, but you had better approach a manufacturer before spending money on patents. We doubt if there is much in it, as the process in question is only practised by very few. In any case we fear that stock size masks would hardly be popular.

SPOTTED NEGATIVES.—I enclose with this three negatives (of no value), and will be greatly obliged if you can assign a cause to the peculiar blotches of silver deposit that appeared on development. The plates were all No. 1 of twelve, loaded into two similar magazine hand cameras. The camera was loaded for a week before use in the case of No. 1 negative, for two days in No. 2, and for four hours in No. 3. None of the remaining eleven plates exhibit any marks. The cameras were made by myself (for stereo work). They are of aluminium, and are lined inside with black silk velvet, glued to the aluminium; at no place is any bright aluminium exposed. I have exposed hundreds of plates in the cameras without noticing any markings, but they were not of this particular brand, and I have not before kept plates in the camera more than a day. The plates are "Imperial NF" brand, the fog is due to an unsafe ruby light, the plates being highly colour-sensitive. The plates in each case were developed (with their complementary 11) in the same tank and with the same developer (rodinal 1-100) that I generally use. There are not particles of metallic aluminium in the cameras, and I brush them free from dust. In their construction there is a little ash wood, rubber, and brass, as well as the aluminium, velvet, and glue.—A. C.

It is impossible to give any definite cause for the markings, but from the information you give it would appear as if the effect is due to some emanation, perhaps from the glue. If you used fish glue or seccotine, or any adhesive of that nature, markings might be expected.

A. HILLS.—We think you will not find anyone prepared to advance the money except on a low estimate of value of the lenses offered as security. We certainly know of no one who makes a regular practice of such business.

VARIOUS.—(2) I have been doing some portraits lately in a sepia tone, mounted on Cosway mounts. As these portraits somewhat resemble old mezzotint engravings, I have thought that I should like to call them "mezzochromes." Should I be within my rights in doing so, or should I be infringing any registered title? (3) If I cannot call them "mezzochromes" can I call them Cosways? Or, if not, can you suggest another name, as I want to describe these portraits in my price list?—CONRAD.

(1) You are in error in saying that the two lenses you name have the same aperture. The portrait lens you say has an aperture of  $f/3$ , but the aperture of the other, for the  $10 \times 8$  size, is  $f/4.5$ . The focus of the latter is between 16 inches and 17 inches, so that with it a distance of about 25 feet would be required between camera and sitter for a full length cabinet portrait. As your studio is but 25 feet long it would not be suitable for full length cabinet pictures. The portrait lens would only require about 18 feet for a similar portrait. (2 and 3) You can call the portraits by whichever of the two names you like.

PINHOLE PHOTOGRAPHY.—I should be very much obliged if you could inform me of the name of a cheap guide to pinhole photography, and also on the construction of a pinhole camera (hand). If, however, you have had an article on this subject in your esteemed journal kindly let me know the date, and I will order the copy.—A. O. PULFORD.

Messrs. Dawbarn and Ward issue about the best guide to pinhole work in their "Photo-Miniature" series (6d.). Your dealer can probably supply you, or you can address the pub-

lishers at 6, Farringdon Avenue, E.C. We would also refer you to the chapter on pinhole work in the "Watkins Manual" (The Watkins Meter Company, 1s.), which contains practically all that is necessary.

PURCHASE OF BUSINESS.—Just about a year ago I bought the above business. It was represented that the returns were — a year, and the net profits —. I was shown the books, which seemed to prove that things were as stated. I have been in the business for a year, and I now find that the returns have been but a little more than half what I was told, and the net profits not half what was represented. Unfortunately, I paid the whole of the money down. Can I recover it back, or any part of it, as the thing is not paying at all, and there is little prospect of its ever doing so, as another photographer has set up close by?—R. A. J.

Unless you are able to show that the books you were shown were fraudulently kept, in order to deceive a purchaser, we do not see how you can recover anything. If action were taken the defence would probably be that your work was not equal to that of your predecessor, or that you did not conduct the business in the same way as he did. Furthermore, that the newcomer had taken some of the business away. If, however, you can prove a fraudulent misrepresentation, you have a good cause of action.

CARBON LANTERN SLIDE TROUBLE.—I have made about three dozen lantern slides by the carbon process, from negatives taken in the autumn, and I am very pleased with them. But on showing them in the lantern a few nights ago I found that the pictures, in several cases, had peeled off the glass. The carbon tissue used was —'s portrait brown. The glass was thoroughly cleaned, and the tissue adhered well in the development, and when the pictures were finished. Ought a substratum to have been used on the glass, and if so, what? Also can you tell me how to prevent the films that are yet intact going like the others?—DISAPPOINTED.

We are not altogether surprised at your experience. The tissue you employed contains a small amount of pigment in proportion to gelatine. Consequently it yields a thick film when the picture is developed. That, with the heat of the lantern, contracted, and hence left the glass. A good substratum is:—

Nelson's No. 1 gelatine, 1 oz.; water,  $1\frac{1}{2}$  pint. When dissolved, add a solution of bichromate of potash, just sufficient to give a plain sherry-colour. Coat the plates with this, and dry them in full daylight, which will make the coating insoluble. With this substratum there will be no danger of the films splitting off. We fear you can do nothing to prevent the other pictures peeling off, if they are allowed to get treated in the lantern as were the others.

APPRENTICE.—Without seeing the indenture, we can express no opinion. We may tell you, however, that if it is not stamped it is of no value. It is not binding on you or on your master. In fact, you are an ordinary weekly servant, and can leave on giving a week's notice, or your master can get rid of you by a similar notice.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The annual index to the "British Journal" and to the "Colour Photography" Supplement is presented as a twelve-page supplement to the present issue.

The full prospectus of the International Photographic Exhibition to be held at Dresden in 1909 is reprinted on page 931. Mr. E. O. Hoppe has been appointed honorary corresponding secretary for England.

Professor Lowell has published the results of bathing experiments as a means of securing fine definition in astronomical photography (Page 977).

A test for the freedom of an instantaneous shutter from jar is mentioned on page 974. It is one which could be applied on a shop counter.

A finder, which also indicates the distance of an object, has been patented. (Page 984.)

The description of the new type of brilliant finder worked out by Herr K. Martin appears on page 979.

A remarkable case of reversal said to be caused by intensification with mercury and ammonia is noted on page 974.

The Royal Photographic Society announces the abolition of medals in both the technical and pictorial sections of the annual exhibition. (Page 973.)

The attendances of officers of the Royal Photographic Society are given on page 983.

Some practical notes on the customary method of glazing gelatin and collodion prints by means of enamel collodion appear on page 976.

We give the conclusion of instructions in the working of the albumen process for the making of lantern slides. (Page 975.)

## EX CATHEDRA.

### Abolition of R.P.S. Medals.

It is announced in the Journal of the R.P.S. that the Council have decided that no medals shall be offered in the next exhibition, in either the pictorial or technical sections. For some time past no medals have been offered in the pictorial section, but their abolition in the technical section is a new feature that will no doubt be received with very varying emotions on the part of prospective exhibitors. In the extracts from the Articles of Association quoted in the Journal we see that article 50 reads: "If awards be given, the judges shall be elected by the members of the society." It follows from this that if no awards be given those responsible for the selection of the exhibits must be elected, not by the members, but by the Council, and it is announced that they will be so elected. In view of this fact the abolition of the medals would appear to have a slight advantage, in that the Council can ensure that the Selection Committee shall include men competent to criticise work in all the various branches of technical photography. This could not be ensured when the committee was elected by the members; but the advantage of a more competent committee is only secured at the cost of abolishing the medals, and it is an open question whether the disadvantages of the old system were sufficient to warrant this extreme course.

\* \* \*

### The Annual Index to the "B.J."

The twelve pages of indexed items which we present with this issue will, we hope, not be overlooked by our readers, but will be bound up by them with the text of "The British Journal of Photography" and of the "Colour Photography" Supplement for 1907. There are many good friends of ours in the trade from whom we hear in the course of the year with requests for information which they might obtain in a moment, as we do for them, if we are asked, by consulting the index to the bound volume of our pages. In the present instance we have made one or two additions, which we hope will still further add to the usefulness of the index to those in the photographic business. Thus the trade names registered during the year are indexed under "Names, New Trade," as are also the names of companies registered, authors of patents, and cases of bankruptcy. Moreover, as we pointed out last week, we have been at some pains to differentiate between the various items under a given heading, as witness the entries under "Blisters on Bromides," "Developer, Developing, and Development," "Reflex Cameras," and "Shutters," to take a few at random. It will be seen from the few cases in which there are a number of references to one item to what degree of thoroughness this process

of identification of each entry has been carried out—at what labour we leave the reader to conjecture.

\* \* \*

### The Making of an Index.

We may be excused for pointing out one or two rules which an indexer needs to adhere to, and a user of the index to bear in mind in looking up an item. An important one is to bring all the items on a given subject under one heading, and to attach cross references to this main section to any others which cannot be brought readily into line. Thus "Screen Plate Colour Processes" are indexed as "Colour Photography—Screen Plate" in the main section, and separate references attached to entries such as Omnicolore, Warner-Powrie, etc. On the other hand, where the sub-division of a subject turns out to be larger than the subject itself, a separate series of items is transferred to another part of the index. This has been done in the case of "Cameras, Reflex," which are found under "Reflex Cameras," to the number of 46 entries. The reader will thus see that the guiding principle to the index is that of subject. The essential descriptive feature of an article or paragraph, such as "Plate," "Camera," "Lens," or "Developer," is that under which it should be looked for in the index. Thus "Eastman Ortho Plates" will be found under "Plates," not under "Eastman." In short, the entries in all cases fine down from the general to the particular.

\* \* \*

### An Index of Colour Photography.

We believe we are consulting our readers' wishes in issuing the separate index to the "Colour Photography" Supplement and incorporating with it the series of items from the "B.J." of 1907 relating to colour photography. The "Colour Photography" Supplement can thus be bound up as a separate publication if so desired, or may be separately collected at the end of the "B.J." volume. A chronology of colour patents having appeared in the course of the year, the "Colour Photography" Supplement will, we hope, be deserving of preserving for reference purposes.

\* \* \*

### Jarring Shutters.

A writer in a contemporary draws attention to the nuisance of a shutter that opens with a jerk and thereby shakes the camera, and, as an alternative to returning the shutter to the maker, suggests taking it to pieces to see what is required in the way of a little watchmaker's oil or scraping! Such advice may be very beneficial to the shutter-maker, but the person who adopts it is likely to regret his action. The little oil will probably upset the working of the shutter altogether, while the scraping will almost certainly be fatal, unless the operator is skilled in the mechanism of shutters. As a matter of fact, a shutter that jumps when it opens is defective in design. Jumping is not an acquired habit, but one peculiar to the design, which in some way or other offends against the laws of mechanics that govern shutter construction. If the defective shutter cannot be changed for one of better make the only effective remedy is to change the camera for a more rigid one. Shutters should always be tested for this defect of jarring before purchase, and the test can easily be made at the dealer's counter. Set the shutter to time, and lay it down on the counter. If this happens to be a glass case so much the better, for the test is then more delicate. Squeeze the bulb and so open the shutter, and note what happens. If the apparatus remains perfectly still it is unusually free from jar. If it moves very slowly and slightly there is not much

the matter with it, but if it gives a decided jerk it may be rejected without hesitation. We possess one shutter that under such a test turns half round, and frequently attempts a somersault. On any ordinary light camera this shutter is quite useless, but on a camera with a rigid front and mounted on a stiff tripod it is very serviceable. Its usefulness is, however, so limited that it is not a desirable instrument to possess. It may be as well to mention that a jerk at the end of the exposure, when the shutter closes, is of no moment. One at an earlier time is fatal, and the time setting is the one with which the defect is generally most noticeable.

### A Strange Case of Reversal.

A very curious specimen of a reversed image has been submitted to us for an explanation of the probable cause of the effect. Unfortunately, however, we are no better able to give one than is the producer of the image. The original, as we are informed, was a rather thin negative, and the owner sought to improve it by intensification with mercury and ammonia. The result is not an intensified negative, but a fairly complete positive, the whole image being reversed with the exception of a small piece of sky seen between some trees. This is as seen by transmitted light. By reflected light it still has the appearance of a negative, whether examined from the back or the front. The appearance is somewhat curious, however the image is examined. By reflected light we see a black negative image on a brown ground, while by transmitted light the whites are white and translucent (not transparent) and the shadows are a deep bluish-black and nearly transparent. The silver deposit thus appears to be still existent in the lights, but to be of a white colour, while the gelatine of the lights seems to have been stained black. The suggestion, therefore, is that the ammonia solution failed to blacken the image completely, while a black stain of some kind was formed in the lights. No doubt there was an error in the procedure somewhere, but we are not able to point out where, as we have never before seen any effect of the kind. We may point out that when viewed as a transparency the positive image is a good one, full of detail. The opalescent whites suggest a backing of opal glass, while the unusual transparency of the shadows escapes notice. Indeed, the result is good enough to render the cause worth investigation, on the chance of finding a new and useful method of converting negatives into positives.

\* \* \*

### Early Photographs.

In view of the strange want of knowledge of the history of photography displayed recently by a "learned counsel," early specimens of photographs on paper are matters of great interest. Through the kindness of a friend, we have been afforded the opportunity of examining two very early specimens, dated 1847. These are Talbot-types tinted in water-colour. Both are very considerably faded, so much so that the photographic origin of one is barely traceable, and it now has more the appearance of a drawing in water-colour alone. The other, however, is still obviously a photograph. Each has an inscription in pencil: "Photograph. Gerethwohl and Tanner, 1847," and they were evidently made at or about the same time. The "touching-up" in ink, colour, and gum is rather crude, but it has saved the results as portraits. Without it they would probably have been unrecognisable by now, but with it they still form excellent portraits of the sitters. They are extremely interesting specimens of early work, and as they are highly valued by their owner, we trust that they will be carefully preserved for a very long time to come.

# A NEGLECTED METHOD OF MAKING LANTERN SLIDES.

In last week's article on the albumen process the preparation and sensitising of the plates were fully described. There are, however, one or two little points that may be added here. The silver bath, after a number of plates have been sensitised in it, will become discoloured, as does the bath employed for sensitising albumen paper. While the colouration is but slight it may be disregarded, but when the bath becomes deeply tinted it must be decolourised. That is done by shaking it up in the bottle with a little pure kaolin. After standing a few hours for the kaolin to subside, the clear portion is decanted off and filtered, when the bath will work as well as when it was first made. The kaolin may be left in the bottle and the solution returned to it each time after use. In this way the bath will be kept quite colourless. Those who make albumen plates for the first time will probably be surprised at their thinness; they are quite unlike gelatine plates, for the film is but very slightly opalescent. We mention this, as some may imagine that there was something wrong with their procedure.

When the coated plates have dried it is difficult to distinguish which is the coated side, and for that reason it is convenient to mark the back. This is best done, after the plate has been coated with the albumen, by attaching a small scrap of paper, using the albumen as a cement. If this is done the cement will be made insoluble when the plate goes into the silver bath, and the paper will remain firmly attached through the after operations.

With regard to the exposure required for albumen plates nothing definite can be said, as all must necessarily depend upon the character of the negative and its density, though with this process there is very considerable latitude; within wide limits errors may be remedied in the development. The process, as we have said, is a slow one, but as an approximate guide we may describe the sensitiveness of the plates as on a par with that of most gaslight papers. The majority of albumen lantern slides are made by contact printing, but they may also be made in the camera from larger negatives, and if a lens with large aperture be employed the exposure is not unduly long. The negatives best suited for albumen transparencies are those of a somewhat vigorous type, such as are best adapted for carbon or platinotype printing, though any kind may be utilised if the development of the image is modified to suit them.

There are several methods of developing the albumen image, all of which yield excellent results, and although the colour of the image, when developed according to some, may be different from that by others, yet all may be made pretty much the same in the toning.

The original method of working was with a saturated solution of gallic acid. The plate was placed on a leveling stand, and some of the solution, to which a few drops of a ten-grain solution of nitrate of silver had been added, was poured on and distributed with a glass rod or a camel-hair brush. By this method the development took a very long time, sometimes two or three hours, according to the temperature and the exposure the plate had received. The image obtained by this method was usually of a yellowish olive-green colour. In the more modern methods of working pyrogalllic acid is the developer employed, and it may be used in different ways, according to taste, yet the results are much the same in the end.

The following is a satisfactory and fairly rapid method of working. A stock silver solution is made as follows:—

Silver nitrate .....	50 grains.
Citric acid .....	50 grains.
Distilled water .....	10 ounces.

Another solution is made as under:—

Pyrogalllic acid .....	30 grains.
Water .....	10 ounces.

The plate is first flooded with water, to which a drop or two of the silver solution has been added. This is allowed to remain on for two or three minutes so as to thoroughly permeate the film, and then is drained off. A mixture of four or five drops of the acid silver solution, with one ounce of the pyro solution, is then poured on and allowed to rest for a minute or so, when, if the exposure has been rightly timed, the high lights should begin to show. The solution is poured off and on until the details are distinctly seen, though they will be thin and feeble by transmitted light. The developer is now poured off, about half a drachm of the silver solution added to it, and development continued until sufficient density is obtained, which should be in three or four minutes, or less, if the temperature is high and the plate has been very fully exposed. If the developer, during the time, becomes muddy, it should be thrown off, the plate slightly rinsed under the tap, and a fresh lot applied. Should the film show stains—as it may do if the development is much prolonged—it is of little consequence if the plate be immediately washed under the tap and the surface rubbed over with a pledget of cotton wool. On continuing the development with a fresh lot of solution, some pressure may be freely used, as there is little fear of the albumen film being injured; its hardness is such that a scrubbing-brush would do it little injury. In any case, it is well to rub over the surface of the film with cotton wool while under the tap before fixing. It may be as well to say here that the development should be stopped before quite sufficient density is obtained, as the image gains strength in the toning. The fixing-bath is:—

Hypo .....	5 ounces.
Water .....	20 ounces.

The plates fix quickly, and the fixing is complete when the opalescence disappears. The picture is then ready for toning. By this method of development the image obtained is of an olive-brown colour.

Another method of development is as follows: After exposure the plate is immersed in a dish of warm water at 90deg. to 100deg. F. It is then flooded with a three-grain solution of pyrogalllic acid, also warmed to a similar temperature. The image should almost immediately appear as quite a phantom one. From its appearance we may judge if the exposure has been rightly timed. If the image appears regularly, as in other processes with rightly-timed plates, it should be slightly rinsed and intensified with the following:—

Pyrogalllic acid .....	30 grains.
Citric acid .....	20 grains.
Water .....	10 ounces.

This is flowed on and off the plate for a minute or two, drained back into the measure, ten or a dozen drops of the silver solution added, and the mixture poured on and off until sufficient density is obtained. If the picture appears at all over-exposed, the silver should be the more liberally used; in the case of under-exposure it should be employed more sparingly. Should stains appear at any stage they should be dealt with as just described. The colour yielded by this method will be of a somewhat less olive tint than by the former one. If by chance by this latter method the high-lights should have a slight pinkish tint—due, most probably, to the plate and solution being made too warm—the fact is of little moment, as the stain will disappear in the toning.

After the pictures are developed and fixed they require to be toned to obtain a pleasing colour. The most satis-

factory bath for albumen transparencies is the hypo and gold bath, made as under:—

Water .....	10 ounces.
Hypo .....	2 ounces.
Chloride of gold (in one ounce of water) .....	4 grains.

After the hypo is dissolved the gold solution is added slowly and with vigorous stirring. The bath should be made about twelve hours before it is required for use. The solution may be used over and over again if more gold is added occasionally, according to the number of plates

toned in it. Indeed, it seems, up to a certain point, to improve by use. The toning is somewhat slow, taking, usually, twenty minutes to an hour or more, according to the temperature and the depth of tone desired. In toning the olive tint passes to a light warm brown, then a deeper brown, warm black, and if continued long enough (with a very strong image) to a purple-black. After toning the plate must be well washed, and is then finished. It will not require varnishing. If it is not convenient to tone the pictures directly they are fixed and washed, they may be allowed to dry, as they can be toned at any future time, when a number may be dealt with at a time.

## ENAMELLING GELATINE AND COLLODION PRINTS.

NOTWITHSTANDING that there has been a steadily increasing taste with the majority of the public for pictures with a matt surface, there is still a demand, among a certain proportion of it, for glazed prints. The fact is evidenced by the number of highly-glazed postcards one sees in the shop windows. If further evidence were required, it is supplied by the queries constantly addressed to us as to the method of enamelling photographs with a collodion surface. The following notes may therefore be of service to many more than those who seek assistance through the "Answers" columns.

### Cleaning and Polishing the Glass Plates.

In the first place some glass plates are required. They should be somewhat larger than the prints to be enamelled, and they must be free from scratches, as any deep ones would show in the finished pictures. The plates must be very thoroughly cleaned; but before that is done the edges should be roughened either by rubbing two together or, preferably, by a ragstone, or a corundum file. It is a good plan also to roughen the edge of the plates the eighth of an inch or so round the margin, as that will give a better hold to the collodion and prevent it springing off as it dries, should it be of a contractile nature. The glass, as just said, must be made thoroughly clean, otherwise the film will be liable to stick permanently. Whiting and water, or, better still, tripoli and methylated spirit are good cleansers, and are both to be applied after the plate has been well washed with soda and water, and rinsed. When the glass has been thoroughly cleaned and polished, it must be prepared so as to prevent the collodion film from permanently adhering. There are two methods of doing this. One is by waxing, and the other by treating it with French chalk.

For waxing the following solution is made:—

Pure beeswax (not white wax) .....	50 grains.
No. 1 benzole .....	10 ounces.

The whole of the wax will not dissolve and make a clear solution, but that is of little moment: the clear portion is decanted for use. A little of this is poured on the plate and well rubbed over with a piece of soft flannel. The surface is then polished with another piece of flannel, so that no streaks or markings can be seen, and the glass looks as if there were nothing upon it. The same pieces of flannel may be used over and over again; indeed, up to a point they improve by use, as they polish better than does the quite new material. Waxing the glass is certainly more trouble than treating it with French chalk, but some prefer it, as they think it yields a brighter surface to the print. If the French chalk be used, it should be dusted over the plate and then rubbed over with a piece of soft rag, with some pressure; the surplus is then dusted off with a broad camel-hair brush.

### Collodionising the Plate.

The plate is now ready for collodionising. A good enamelling collodion is made as under:—

Pyroxyline (not powdery) .....	100 to 120 grains.
Methylated spirit .....	10 ounces.
Ether .....	10 ounces.
Castor oil .....	4 or 5 drops.

The pyroxyline should be put into a bottle with the spirit, and well shaken before the ether is added; it then dissolves rapidly. When dissolved the castor oil is added. The collodion should be allowed to stand for a day or two for any undissolved particles to subside, when the clear portion can be decanted for use. Some pyroxilines yield a more viscous collodion than others; but if with the larger proportion, given above, it should prove too thick to flow freely over the plate, more ether and spirit can be added. Enamel collodion, ready for use, is supplied commercially at a low price, and many prefer to buy it rather than have the trouble of making it.

### Applying the Prints.

The plates, prepared as already directed, are coated in the usual manner, and when the collodion has very thoroughly set are put into a tray of cold water and allowed to remain, with occasional agitation, until all traces of the ether and alcohol are washed away. This may be known to be complete when the surface of the collodion ceases to appear greasy. We must now have ready the following gelatine solution:—

Nelson No. 1 photographic gelatine .....	1½ ounces.
Water .....	1 pint.

The gelatine should be soaked in the water (cold) until thoroughly softened, and then dissolved by heat. This, after straining through muslin, is put into a dish, which is placed in another containing hot water to keep it warm—about 120 deg. Fahr. The print to be enamelled is immersed face downward in this for a minute or two. The plate, after rinsing under the tap, is then slid, collodion side upwards, under the print, the two brought into contact, removed, and squeezed together. A piece of thin india-rubber cloth—that known as nursery sheeting is best—is laid over the plate so that the squeezing does not injure the collodion, as, if it did, it would have a tendency to split up before the print upon it were dry. If it is gelatine prints that have to be enamelled, they should, previously, be hardened, either by alum or formaline. Otherwise, with some papers, the warm gelatine may have a tendency to dissolve that of the print. The plate may now be put away to dry. When thoroughly dry, and not before, the print can be stripped off, and will have an exceedingly high gloss. Much of this, however,

may be lost in the mounting, if the print be put direct on the print. Therefore, it is better, after the plate and print has been exposed for an hour or so, to put another sheet of thick paper upon it. This paper should be soaked in the hot solution of collodion until it has fully expanded, and then be squeezed on the back of the print. In place of using plain paper for this purpose, thick double transfer paper, as used in the carbon process, is more convenient in use, as it requires only to be heated in warm water to be at once ready for squeegeeing upon the print. With small prints a number are, of course, put on the large plate, and a great saving of time thus effected.

**Trimming and Mounting.**

When the prints are stripped off the glass they are trimmed, and that is the more neatly done with one or other of the cutting machines now on the market. They are best attached to the mounts by a little glue applied just round the edges of the pictures. When the prints are stripped off, any collodion adherent to the glass should be scraped off with a knife, and the plates will then be ready for use again, simply by polishing with wax, rubbing them over with French chalk. Indeed, the more the plates are used, provided they are not wetted, the less waxing or rubbing they will require to prevent the collodion sticking.

**Enamelling with Celluloid.**

The above is the method most generally adopted, yet a far better way, and one that involves much less trouble, is to enamel with thin celluloid. This, however, requires a special, but not expensive, appliance, consisting of an iron slab, and a heavy iron roller, weighing from three-quarters of a hundredweight to a hundredweight, according to size, and some eight inches in diameter. The roller is heated, from the inside, by gas supplied by a flexible tube, and made as hot as the hand can well bear. The print to be enamelled is immersed, for a minute or so, in methylated spirit, drained, and laid, face upward, on the slab, with two or three thicknesses of blotting-paper below it, to absorb the superfluous spirit. A piece of the celluloid is then placed on it, and the heated roller passed slowly over it two or three times. The celluloid is thus caused to adhere firmly to the print. It will be seen that this system of enamelling involves far less trouble than that first described. It also has the advantage that the surface of the celluloid, being so much harder than that of collodion, is not so liable to become abraded by slight friction. Thin celluloid suitable for the purpose is sold in sheets 36 by 20 inches, and can, of course, be cut to any size.

WILLIAM MICHELL.

**A NEW MEANS OF SHARPENING CELESTIAL PHOTOGRAPHIC IMAGES.**

(A communication to the current issue of "Popular Astronomy.")

Among the many devices, combination of which has made possible the successful photographing here of Mars, enabling the canals of the planet to print their own record on the film, next to steadiness of air, the more vital than the approximate monochromatisation of the light, got by the use of a suitable colour screen placed in the cone of light before that reaches the sensitive plate. For by means of this device is attained the practical unity of focus essential to definition, was by application of the principle that Ritchey secured his excellent pictures of the moon which marked so great an advance in celestial photography, and a colour screen of much the same character was first employed here by Mr. Lampland in photographing Mars, specially designed by Mr. Wallace for the colour-curve of the planet.

The planet, however, is a much more difficult subject for photography than our satellite, inasmuch as the markings desired are of a finer texture. To reveal the canals involves the getting of a definition far surpassing that sufficient to make beautiful portraits of the moon; as the scale upon which the two pictures are made is not enough to show. Now several things militate against the obtaining of sharpness of delineation of the degree required for the registering of planetary detail. Chief, of course, is unsteadiness of the air, which rarely permits approach to perfection in the image. Next comes the chromatism of the telescope. While, lastly, linked for bad results with both, is the relative insensitiveness and granularity of the photographic plate. It is the latter's comparative slowness of action and coarseness of grain that renders the eye the more delicate instrument in decipherment of the sort. Nevertheless, owing to a suitable prolongation of the effect, and to the accentuation of contrast secured by the film, the camera has recently done some surprising work in the case of Mars in registering what, without its prompting, the eye had failed to detect.\* The main proposition, however, remains true. For accuracy of form in the Martian markings one must be recommended to the eye, for the finer detail comes out by flashes of prolonged exposure results only in a blur.

To reduce the time of action to its shortest compass is thus one of the essentials to success. On the other hand, to shorten the time to reduce the light, and a modicum of light is necessary to securing an image in which the finer detail shall show. Here again the plate is at a bar in the coarseness of its grain as compared with the

On one of my plates at this opposition a canal stood recorded where none had previously disclosed itself. On searching for it visually the next night, the canal was seen for the first time.

markings to be registered, since to magnify the image much is prohibitive to the getting of any revelation at all. What has been said will give some idea of the difficulties to be overcome.

It is evident, then, that two points must be assured. Enough light action on the one hand and approximate monochromatism on the other. To attain these two results has been one of Mr. Lampland's exhaustive studies in this field for the last four years. He has carefully tested all kinds of plates, and we have even gone so far as to try to get new plates made for us.

During this time Mr. V. M. Slipher had been engaged in experiments upon bathing plates for extension of action into red. His

COLOUR CURVE OF LOWELL REFRACTOR.

The ordinates represent focal distances in millimeters; the abscissae, wave lengths of the spectral rays.  
(Positions determined by Mr. V. M. Slipher.)

remarkable success led me to a new departure. Mr. Slipher's plates were for spectroscopic purposes, but in considering the colour-curve of the 24-inch objective, it occurred to me that another use might be made of them, to wit: that unity of focus might be more nearly approached without loss of light by bathing the plates in suitable solutions for prolongation of their sensitiveness into the red, and then cutting off the light of greater focal length toward the blue by a colour-screen specially contrived for the purpose. By previous colour-screens the light admitted had been made up of rays extending from wave-lengths  $\lambda = 4660$  or  $\lambda = 4700$  to the extreme limits red-wards

of the sensitive plate which in the case of unbathed plates stopped in the yellow; even Cramer's Instantaneous Isochromatic only going to  $\lambda = 6000$ .

Now, according to the colour-curve of the 24-inch objective, and for that of Clark's glasses generally, the light waves for  $\lambda = 4600$  are not brought to the same focus as those for  $\lambda = 6000$ , falling in the case of the 24-inch some 12-mm. beyond it. Light from them, therefore, is worse than useless in the formation of the image where form is what is sought. For though they add to the intensity, they detract from the definition. To secure the maximum effectiveness the problem consisted in integrating, as it were, the illumination within such limits as to give sufficient light with the least focal deviation between the different rays. Their intensities had to be summed, weighted for their respective focal lengths.

Investigation on my part indicated  $\lambda = 5000$  as the blue-ward limit of the light to be admitted to attain the best result. Accordingly I asked Mr. Wallace to construct for us both a solid and a liquid filter to cut off all the rays up to that point, which, with some difficulty for precision, he very successfully did.

The colour-curve of the objective is given in figure 1, the ordinates representing the focal length, the abscissæ the wave-lengths of the several spectral rays. It will first be noticed that F,  $\lambda = 4861$  and B,  $\lambda = 6875$  have the same focus, the result striven for by Clark in the grinding of the glass; and, secondly, that any light of less wave-length than F has a focus further out, increasingly so as the wave-length is decreased. Also that the curve is flatter, or in other words, the focal distances of neighbouring rays differ less from one another in the region of the yellow or about  $\lambda = 5600$  than in any other part of the spectrum. The nearer the rays to be used are, therefore, to this minimum focus the less the resulting image will be blurred, and especially must the rays at the blue end be excluded, as the focal curve falls much more rapidly on that side than on the red.

Turning now to the combination-bathed plates and selecting two, we perceive one bathed with pinaverdol and pinacyanol, the other with pinaverdol, pinacyanol and pinachrome (figure 2); that their curves of sensitiveness run approximately level from a minimum at about  $\lambda = 5000$  to  $\lambda = 6500$  and  $\lambda = 6800$  respectively, or in the case of the latter from about F to B, and of the former from F to C; both including far more of the red rays than the unbathed plates. By bathing, therefore, enough rays could be secured at the red end to offset the loss of light from cutting out those between  $\lambda = 4600$  and  $\lambda = 5000$ , and at the same time secure a less deviation in their integrated focal lengths. With the plate bathed in pinaverdol and pinacyanol, one should be able theoretically to obtain as much illumination as with an unbathed one, after cutting out all the rays below  $\lambda = 5000$  and, with a total deviation in the extreme focal lengths of only 4.4 mm. as against 12.4 mm., or but a third as much, not to mention the fact that in the unbathed the intensity of the out-of-focus rays is relatively much greater. The conception was theoretically sound; it only remained to see if it would work in practice.

The screen was first tried on Seed "23" plates bathed in a solution of pinachrome and pinacyanol under Mr. Slipher's able manipulation, and then exposed by me at the telescope. Owing to the unavoidable introduction of other factors, increased length of exposure principally due to the relative slowness of the Seed "23" further accentuated by the bathing, the result was not successful, Mr. Slipher being of the opinion that the developer used, pyro, had some hand in the failure. Whatever the cause, desire to get photographs of the planet induced me to defer the experiment in this form, though I hope to take it up later. In the meantime I applied the device to Cramer's Instantaneous Isochromatic plates, and this time with success.

The curve of sensitiveness of the Isochromatic plates, Fig. 2, is peculiar. Though the plate is called the Isochromatic Instantaneous.

it is neither isochromatic nor instantaneous, and stands justified on its name only on the syllogistic ground that two negatives make an affirmative. But its very lack of isochromatism proved its salvation. For, in it we note two maxima, one about  $\lambda = 4600$  and another at  $\lambda = 5650$ : while a minimum exists at  $\lambda = 5000$ . The theoretical difference here, between the action of the two screens, is evident at a glance. The yellow or old one admits out-of-focus rays of theoretically great intensity between  $\lambda = 4600$  and  $\lambda = 5000$  which the orange screen at  $\lambda = 5000$  entirely cuts out.

Exposing a plate of this kind on Mars in our usual way—a method by which fifty or more images are taken consecutively on a single plate in a few minutes—I took half the number behind the old screen and then replacing it by the new one, took as many more, both sets being exposed equally, about two seconds being given to each image. The plate was then developed as a whole. The result stood self-

#### CURVES OF SENSITIVENESS OF PHOTOGRAPHIC PLATES.

- d. Seed 20 unbathed.

Fig. 2.

confessed. The detail came out sharper in the images taken with the orange screen than with those taken with the yellow, although the images of the former were not quite so dense on the average, showing that in their case a slightly longer exposure would generally be necessary.

In order to be sure that the outcome was not due to change in the seeing during the interval, short as was the time between the first image and the last, I later exposed another plate in the same way, and to the like conclusion. The orange screen gave the sharper definition, while the exposure time for effect was about as 7 to 6.

The bettering of the image was much greater than I had anticipated, and than the spectrograms taken with the two colour-screens respectively, and here reproduced, would show. I regret that it is out of the question to reproduce satisfactorily the images showing the success of the theory, for the improvement, though evident in the original prints, loses too much in definition by reproduction processes.

This improvement has come too late to affect our results at the opposition, but I trust to put it in practice at the opposition of two years hence.

PERCIVAL LOWELL.

ROYAL ALBERT INSTITUTE, WINDSOR.—A photographic exhibition will be held in the above institute on February 19 and 20, 1908, under the patronage of T.R.H. the Prince and Princess Christian of Schleswig-Holstein, the Mayor of Windsor, Viscount Maitland, Sir Benjamin Stone, and other distinguished personages. There will

be both open and local classes for amateurs and professionals, in each of which (with the exception of one class) a bronze plaque will be placed at the disposal of the judges for award. Entry forms are now ready, and may be obtained from the secretary, Mr. J. W. Gooch, 9, High Street, Windsor.

## A NEW TYPE OF BRILLIANT FINDER.

[The following description of the new mirror-finder, designed by the inventor of the instrument appeared in *THE BRITISH JOURNAL OF PHOTOGRAPHY* for October 18 last, on the occasion of the publication from the inventor will perhaps better explain the advantages of the

INCITED by the frequent complaints of the ordinary finder in

Fig. 1.

the autumn of 1906, I took up the question of making one on an entirely new principle, which should do away with all the disadvantages of the existing types.

The ordinary Newton finder (the direct vision concave lens—Eds. B.J.) is certainly satisfactory to a great extent, but the chief disadvantage is that the camera must be held level with the eye. Although this is undoubtedly the correct position, it is not a favourite one with amateurs for the reasons it is not comfortable

Fig. 2.

and renders it difficult to work unnoticed. The ideal finder for amateurs is one that can be looked down on.

A good finder should fulfil as far as possible the following requirements:—1. The image must be as large as possible and the right way round, not upside down or reversed. 2. The finder must be free from troublesome reflections and be very brilliant, so that it can be used in the open in bright light, a point in which many brilliant finders fail.

The fulfilment of these conditions appeared to me to be most readily effected by means of a mirror. If a spherical concave mirror is placed in the line of sight (Fig. 1.) and looked in from above a bright, clear picture of an object is seen, which is, how-

ever, very badly distorted and reversed as regards right and left, as with all finders that are looked down on. I considered that the distortion could be cured by departing from the spherical form and the thought occurred to me to give it the form of a convex instead of a concave mirror across the meridian (paper) plane.

At the risk of being considered an absolutely empirical or rule-of-thumb worker, I may state that the first experiment was made

Fig. 3.

with a Benedictine bottle, the neck of which has something of the desired shape. The experiment was a complete success.

The surface of the finder-mirror must therefore have a double curvature, the so-called saddle surface, a shape which, so far as I know, has not been previously used in optics. There is no great difficulty in making such a surface. The desired surface is a section of a so-called "chamfer." (Fig. 2.)

In order to obviate the rather great distortion remaining, I gave the convex (side) curvatures different values in zones. This can be easily done by choosing a chamfer (Fig. 2), in which  $a$  has a greater diameter than  $b$ . Obviously, one can calculate mathematically the surfaces, so that every distortion would disappear. For photographic work the above method, however, is quite satisfactory.

The mirror surface of the new finder, "Sellar," is extremely interesting optically. It is hermaphrodite, in the direction of the line of sight it is concave, but at right-angles thereto convex. It

Fig. 4.

is impossible, therefore, to project an image by means of the finder on to a ground glass, as one would obtain instead of points image lines, and the latter, corresponding to the principal curvatures of the mirror, are partly real and partly virtual. When looked at the two constituent images merge into a single bright, clear image, in consequence of the slight accommodation of the eye.

The new finder, which has been introduced commercially by the Rathenower Optische Industrie-Anstalt, formerly Emil Busch, under the name of "Sellar" for the various foci and sizes of plates, is shown in Figs. 3 and 4. It takes up no more room than the usual concave finder. It may also be mentioned that the new finder and its various modifications have been protected in Germany and other countries.

K. MARTIN.

MR. WALTER POUNCY, of Dorchester, on Saturday last received a letter from Count Paul Wolff-Metternich, the German Ambassador, stating that the German Emperor had been graciously pleased to accept two large photographs of Corie Castle, which Mr. Pouncy had sent him, and conveying to him his Imperial Majesty's best thanks for the gift.

BLAIRGOWRIE PHOTOGRAPHIC ASSOCIATION.—At the last monthly meeting a very handsome volume, "Women Painters of the World,"

was presented to the Association by Mr. A. Geekie, Coupar Angus, the president, who was very cordially thanked. The result of the "Flower Study" competition was announced—1 and 2, W. D. M. Falconer; 3, D. G. Monair. A large number of prints were handed in for the "Figure Study" competition. An interesting manuscript magazine was submitted and read by Mr. L. Falconer, jun., the editor, and was favourably criticised.

## A SUGGESTED SYSTEM OF DEVELOPMENT.

HERR KÖNIGLICHER UNGARRISCHE SEKTIONS-RAT PAUL VON JOANOVICH, of Budapest, in the current number of the "Photographische Korrespondenz," makes the following statement as to his particular system of development. If borne out in practice his suggestions should certainly revolutionise our present methods of working.

Among other advantages claimed for the process are its rapidity and cheapness. Two tanks are used. One is filled with a solution of

I. Metol .....	5 gms.
Hydroquinone .....	5 gms.
Sodium sulphite .....	100 gms.
Water .....	1,000 ccs.

The other with

II. Potassium carbonate .....	100 gms.
Water .....	1,000 ccs.

Twelve plates, placed in a metal rack, are lowered into the tank containing Solution I., are moved up and down to dislodge any air-bells, and then left for thirty seconds. The rack is then removed and placed in the potash (II.) solution for 30 seconds, then instantly rinsed and fixed. Single plates may be treated in flat dishes in the same way.

As the plates are removed from the Solution I. after half a minute, only just the amount of the reducing solution which can be taken up by the gelatine in that time is used. This quantity is so small that when the plates are placed in II. solution, over-development cannot occur, and the silver bromide is reduced in proportion to the exposure. If the exposed particles of silver bromide are reduced, and the small

quantity of absorbed developing agent used up, the action stops, since there is no longer any reducing solution present. The unexposed parts are not affected in the presence of the minimum quantity of the reducing solution absorbed in the first tank. Fog cannot form, hard negatives are extremely rare, as this defect is mostly caused by prolonged treatment of the plate in the hope of developing the unexposed portions. As the developing solution is allowed to act equally over the whole plate, the more fully exposed parts are over-developed, or fog is caused. By the new method this danger is as good as excluded.

The cheapness of the process is due to the fact that the Solution I. can be repeatedly used, as the quantity of solution absorbed by the plates is very small.

Solution II. is the only one which suffers. After every fifth or sixth dozen plates a fresh solution must be made up.

Another advantage according to the author is that the process is purely mechanical. Control of the plates during development is not required, is, indeed, useless. (We would also add impossible.—Eds., "B.J."). What is exposed is promptly reduced. Thus the process is simple. Everyone able to follow the very simple directions can immediately develop with excellent results. The process should therefore appeal to beginners.

Another advantage claimed by the author is that on his system development can be carried out in total darkness.

It should be added that every developing agent, with the exception of amidol, which requires no alkali, can be used for this method. All alkalies, either carbonate or caustic, may be used.

## FLOWER PHOTOGRAPHY.

(The Abstract of a Paper read by Mr. E. Seymour before the Royal Photographic Society.)

MR. SEYMOUR said that in his little studio, which was a coach-house, he softened the light by means of art muslin. The width of the place was 4ft. 9in. He did not believe that it was necessary to work eight or nine feet away from the source of light, and all his studies were made within two feet of the glass. He had a packing case and a drawing board on which he arranged his studies. For backgrounds he used picture-framers' cards, choosing the shade according to the subject, so as to obviate hardness. He carried out the work of arrangement by means of wires and pins of various sizes. He fastened the flowers right on to the background, thereby giving them shadow and strength. The pins, even when liberally used, were not at all obtrusive in the resulting photograph. When seen, he said, they looked like dewdrops. He claimed that in some cases the pin or nail improved the result, a three-inch nail in a branch of apples study appearing like a bit of rugged bark. With pansies he used wires instead of pins. He did not often use vases as receptacles for the flowers, finding that they gave a top-heavy appearance to the arrangement. When he did use them he used also a lighter background, and tried, by keeping the vase in the shadow as much as possible, to make it merely an after-thought of the picture. In some cases he used scooped-out potatoes as receptacles for the flowers, and when tablecloths were needed to complete a study he used brown paper, which was cheap and effective, all the more so if it had previously been used for packing.

He used an ordinary studio camera and studio stand, and a whole-plate Goerz lens made to cover 12 x 10 by stopping down. His favourite plate was the Barnet orthochromatic, but he rarely used a screen. He was able so to select his colours that blue rarely came into his compositions, and therefore the main reason for the use of a screen disappeared. With regard to the exposure, if he found it necessary to give ten seconds for the white, he would give twenty seconds for the yellow, and, if bordering on orange or deep yellow,

forty seconds. In fact, he continually over-exposed, giving the yellow colours the opportunity, as it were, to fix themselves upon the plate. He admitted to a partiality for yellow flowers, which he photographed in preference to all others. In many cases, such as the poppy and other delicate blooms, the exposure needed to be fairly rapid in order to obviate difficulty arising from the movement of the flower and the curling of the leaves.

In development he used the "Imperial pyro-soda" formula, less the bromide, which he found clogged the shadows. His practice was to take three ounces of No. 1 to half an ounce or one ounce of No. 2. The secret of success in flower photography was to expose for the shadows and develop for the high-lights. Directly the highest light became sufficiently dense, so that the texture could just be seen, and the other high-lights were beginning to appear, he took the plate out of the developing bath, and put it into the hypo solution; there was no time for washing. If it had been under-developed he could always build up the image with mercuric iodide. Prolonged development would give him contrast, but at a sacrifice, for the succeeding half-tones following in the wake of the highest light, which was already dense, would join forces, as it were, to extinguish the detail in the high-lights, just where it was above all things needful in flower photography. He did not mind how flat the negative was, he could build it up as much as he pleased by intensification. But if development were allowed to go on in the ordinary way it meant the disappearance of texture and softness.

Proceeding to speak of composition, Mr. Seymour said that he first conceived an idea of what he wanted, and then made his subjects "go that way." He was at first in the habit of photographing his flowers as soon as possible after they were picked, but now he always picked them over-night, kept them in a cool place, and photographed them the next morning, when they showed up quite fresh, except dandelions, which were not amenable to that form of treatment.

He laid stress on the value of side-lighting. In some cases he turned his studies away from the light, at an angle of 45 degrees. Texture and light and shade were lost if the subject were too much to the light, while beautiful effects could be produced when the light just caught the tip of the flowers. He dwelt upon "the art of leaving out," and impressed upon his audience the necessity of judging the arrangement through the camera. Many studies, he said, appear to be beautiful to the eye, but, seen through the camera, were shown at once to be too crowded and lacking in simplicity to be effective as photographs.

He showed some excellent results in fruit photography, and said that the best tone value photograph he had ever produced was one of a bunch of black and green grapes, which was remarkable for the strong shadow and texture of the fruit. Grapes with much bloom were bad from a photographic point of view. Leaves often lent themselves to beautiful compositions, although as a general rule the aim should be to have the leaf noticed last of all. Raspberry leaves and the leaves of the pink American currant were particularly good. The structure of the leaf of the nettle was also very beautiful. It was Rodin who said that there was as much beauty in a leaf as there was in a mountain, if only we were able to see it. Mr. Seymour found it useful, just before exposing, to wet the green leaves with a sponge of cotton wool, the greens appearing much lighter when wet. One of the advantages of flower photography was that the artificial was often indistinguishable from the real, and on one occasion, wanting some flowers to complete a composition, and finding none available, he took some flowers from a picture hat, thereby making a very effective study. Mr. Seymour added that his best picture, which had been sold fifteen or twenty times over in the exhibitions, was a study of currants, and owed its arrangement to the suggestion of a friend. The arrangement displeased Mr. Seymour at first, but he ultimately decided to waste a plate upon it, with the above result. One of the flowers which gives hard prints, he said, was the dahlia, on account of the heavy shadows which it casts.

#### THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION, DRESDEN, 1909.

In publishing the English version of the prospectus of the proposed International Exhibition of Photography, to be held in Dresden in 1909, we should mention some few of the names of those who have consented to serve on the Council of Organisation. Among the well-known Continental authorities who have thus given the exhibition their support are: Herren R. Dührkoop, Hugo Erfurth, Heinrich Ernemann, the well-known maker of cameras, C. P. Goerz, Fritz Hansen, and Franz Goeke, Ernst Juhl, Fritz Loescher, L. Mayerhofer, director of the Peütz plate factory, Dr. Adolf Miethe, Dr. Neuhaus, Dr. Schultz-Hencke, and A. Schwarz, of the Neue Photographische Gesellschaft.

The exhibition will have solely for its own purposes the large block of buildings erected by the Dresden Municipality, and including 1½ acres of covered space and 16 acres of grounds, where, from May to October, 1909, a collection of exhibits is to be brought together, which it is hoped will be thoroughly representative of the photographic art, science, and industry of all countries. We understand that in the sections devoted to the photographic trade competition for the awards will be between exhibitors of each separate country only, a policy which should relieve the management from the charge of favouring their own country above others.

The general offices of the exhibition, whence the prospectus may be obtained on addressing a postcard, are Hotel Stadt Berlin, 1 Neumarkt, Dresden, but we understand that Mr. E. O. Hoppe, F.R.P.S., of 10, Margravine Gardens, Baronscourt, London, W., has been appointed honorary secretary of the exhibition for England, and is prepared to deal with inquiries of a general nature and to refer them to the proper quarter in Dresden.

The following is the official prospectus of the exhibition:—

The International Photographic Exhibition, Dresden, 1909, is to be a collective representation of Photography in all its branches and in all civilised countries. It is proposed to show the evolution of Photography and its achievements in Art, Science, and Commerce, its technical application and its various branches.

To this end the following classes have been arranged:—

#### I.—EVOLUTION, SCIENCE, AND SPECIAL APPLICATION OF PHOTOGRAPHY.

- (a) History of Photography.
- (b) Colleges for Photography.
- (c) Photographic Literature.
- (d) Scientific Photography.
  1. Astronomical Photography.
  2. Meteorological Photography.
  3. Botanical Photography.
  4. Zoological Photography.
  5. Anthropological Photography.
  6. Pathological Photography (including Röntgen Ray Photography in Medicine).
  7. Photography for Mineralogical and Geological Purposes.
  8. Balloon Photography.
9. Photogrammetry (including Architectural and Geometrical Photography).
10. Photography in Museums and Libraries.
11. Photography in Government, Administration of Justice, Trade and Public Committees.
12. Photography in Physics.
13. Photography in Chemistry.
14. Photography in Scientific Research and Experiments.
- (e) Ethnological Photography.
- (f) Entertainment and Instruction by Photography.
- (g) Colour Photography.

#### II.—COMMERCIAL PHOTOGRAPHY.

- (a) Professional Photography.
- (b) Photographic Reproduction Processes.

#### III.—AMATEUR PHOTOGRAPHY.

#### IV.—PHOTOGRAPHIC INDUSTRY.

##### I a.—HISTORY OF PHOTOGRAPHY.

This class will be divided into:

- (a) History of Pictorial Photography.
- (b) History of Technical Photography.

It is proposed to show as far as possible everything which has played an important part in the invention and evolution of photography. The pictures will be shown in chronological order, when possible with particulars as to authorship, the year of production and the process employed. Where it is thought of importance a short biographical note of the author will be given, with account of what practical value his work has been to the development of photography, and its relation to later improvements.

In a separate sub-division there will be a portrait gallery of those whose work and investigation have been of special value, possibly with particulars of their work. Also all available documents, manuscripts, and letters in any way relating to the history of photography, will be included here.

There will further be a special class to demonstrate the evolution and extension of photography as applied to technical, artistic, and scientific purposes, and the revolution photography has brought into the technique of pictorial reproduction, together with its influence on various departments of civilisation.

Under the history of technique will be shown all appliances, lenses, apparatus, and other articles used at any time for photography, in chronological order. The objects will have the names of the authors, the year of production, and all further particulars attached.

Illustrations of the history of photographic industry will be found here, such as photographs of the making of the camera, of the manufacture of lenses, of the production of plates and papers, the way in which the technical articles were first used, and their development from simple handiworks into objects of wholesale manufacture.

Under this class will also come statistics and all particulars of the national domestic importance of photography and the industries connected with it, with reviews of its present strength and standard professionally.

This class will be thoroughly international—that is to say, it will not be separated into different countries; only chronological order will be maintained. It may possibly be divided into periods. All objects shown under History must have been in existence for at least five years.

Trophies will be given.

##### 1b.—COLLEGES FOR PHOTOGRAPHY.

In this division will be exhibited the arrangements, appliances, and working methods of existing schools and colleges, with particulars of their different aims and degrees of success. It will be a means of comparing what has been achieved in the way of photographic instruction and showing how it is done.

A special division will contain testing apparatus for lenses, plates,

and papers, with method of employment, and the arrangement of photographic laboratories.

This class will be divided into countries.

Trophies at the discretion of the jury.

#### I c.—PHOTOGRAPHIC LITERATURE.

There will be no sub-divisions in this class, except as to languages. It will take the form of a library and reading-room, furnished with all writing requisites. All books and periodicals relating to photography, or any branches connected with photography, will be admitted.

Trophies at the discretion of the jury.

Class prize: Plaques for special merit.

#### I d.—SCIENTIFIC PHOTOGRAPHY.

This class will be divided in the manner before stated.

Further classes may be added.

The arrangement of these classes is international. The whole Scientific Division is to give a complete survey of the employments photography finds for scientific purposes. No special qualities will be demanded in the pictures, but they must show the object depicted in a clear and correct manner; they must also be technically perfect. Details as to object photographed, purpose of picture, and its relation to science, and, where feasible, manner of taking, apparatus used, etc., should be given.

The classes will be again sub-divided, so that each part will afford a general view of the whole of that branch. In such a division there can be shown special apparatus and expedients used, so long as they are not objects of industrial produce.

Trophies.

#### I e.—ETHNOLOGICAL PHOTOGRAPHY.

In this division all the larger countries of the world are to exhibit their particular beauties in nature and art, or the characteristic features of their people and land. The colonies should, for the time being, incorporate themselves with their mother-country, so that this exhibition, which is to be in the principal hall of the Exhibition Buildings, will afford a view of the beauties and characteristics of the nations of the whole world.

Naturally only a rough idea of the countries will be obtained in this way, but, all the same, it should prove instructive to the public in general, and reveal fresh fields of interest to the large proportion of travellers who visit Dresden.

A few objects relating to the art and ethnography of the different nations are to be depicted here to complete the picture. The whole is to form the great central point of the Exhibition, to emphasise the internationality of its character and to show the sphere of representation from which the various classes are made.

#### I f.—ENTERTAINMENT AND INSTRUCTION BY PHOTOGRAPHY.

This class will be divided into:—

Stereoscopic Photography.	The Optical Lantern.
Cinematography.	Methods of Photographic Instruction.

Each division will be sub-divided according to countries. Pictures and all kinds of apparatus, light arrangements, etc., relating to any of the above branches, will be shown. It is intended to fit up stereoscopic panoramas, revolving stereoscopes, and to give lantern lectures, cinematographic displays, etc.

It is proposed to show here to what extent photography is used for instruction in schools, etc.

It has further been arranged that regular lectures shall be given in the separate divisions of the Exhibitions, such as portraiture, astronomical photography, etc., with practical demonstrations.

Trophies at the discretion of the jury.

Class Prizes: Diplomas for gold and silver medals.

#### I g.—COLOUR PHOTOGRAPHY.

This class will be divided into countries. It is proposed to show here everything of practical importance in the employment of colour photography. The pictures will not be judged as to artistic merit, but they must be the sole work of the exhibitor, and produced by photographic means. Details must be supplied as to technique employed. Unlike in the other divisions, apparatus and appliances

of colour photography may be shown at the same time. Demonstrations of the various colour-processes may possibly be given.

Trophies.

#### II a.—PROFESSIONAL PHOTOGRAPHY.

This class is divided into:

Portraits.	Landscapes.
Groups and Genre-pictures.	Technical Photography.

A division into countries, towns, and, if advisable, societies will be made. Pictorial merit will be demanded in the pictures shown, and a jury will be appointed for judgment. Only those using photography as a profession will be eligible in this class. The method of production is optional, but prints should not be smaller than half-plate size, and must be the sole work of the exhibitor, or emanating from his or her studio. All pictures must be sent in framed.

In the technical division prints of a commercial and technical character, such as photographs of machinery, or for posters, calendars, decorative purposes, etc., will be exhibited. Also in these pictures a certain standard of artistic merit will be demanded in so far as compatible with the nature of the photograph. The object of this class, as a whole, will be to show the present-day standard of professional photography in portraiture, landscape, or illustration.

Trophies.

Diplomas for gold and silver medals.

Placing "hors de concours" by the jury will be the highest distinction in this class.

#### II b.—PHOTOGRAPHIC REPRODUCTION PROCESSES.

The following divisions will be made:—

(a) Direct Photographic Reproduction (including rotary printing, pictorial postcard printing, photographic ceramics, etc.).	(b) Indirect Photographic Reproduction (including photo mechanical processes, such as photogravure, half-tone, and block-making).
---	---

This class will be divided into countries. Here are to be shown as far as possible not only the results of all different kinds of technics and processes in photography, but also their manner of employment, if feasible by the representation of the printing machines at work. The process of block-making in all its different stages, from the first taking of the photograph to the finished printed article, will be shown. All materials, machinery, raw products, papers, etc., used in the reproduction of a photograph will be included here.

Diplomas for gold and silver medals.

Trophies at the discretion of the jury.

#### III. AMATEUR PHOTOGRAPHY.

This class will be divided into:—

Portraiture.	Landscapes.
Groups and Genre Pictures.	

There will be sub-divisions into countries, towns, or societies. Pictorial merit will be demanded in the pictures shown, and a jury will be appointed for judgment. Only amateurs will be eligible. The method of production is optional, but prints smaller than half-plate should be avoided, and each picture must be the sole work of the exhibitor.

It is proposed to give in this class a comprehensive representation of what has been achieved by amateur photography. On account of the large number of productions in this field only the best can be admitted for exhibition.

Trophies at the discretion of the jury.

Class Prizes: Plaques.

#### IV.—PHOTOGRAPHIC INDUSTRY.

The following divisions will be made:—

Cameras and Lenses.	Photographic Papers.
Dry Plates and Films.	Photographic Apparatus.
Chemicals.	

The sub-divisions will be according to countries.

This class, which will probably be the largest in the Exhibition, will give a general idea of the industry photography has created. It is proposed to show here cameras, lenses, plates, etc., not only as finished articles, but also during the process of their manufacture from the raw products. These raw products will be displayed, and the machinery used in the manufacture of each article will be shown at work. There will be illustrations of the manufacture of lenses, the making of glass plates, machinery for preparing sensitive plates

and papers, and the exhibition of raw paper and other materials with demonstration of their process of making. Methods of artificial lighting, studio construction and arrangements will be exhibited.

This collection of articles of manufacture is to be on a larger scale than any hitherto made, at the same time it is not to simply consist of a meaningless heap of dry plates, printing paper, glasses and bottles, incomprehensible to the general public, but it is desired that the apparatus, lenses, etc., shall be shown opened out and in sections, the comparison of plates and papers exemplified by actual results; in short, each exhibitor should display his originality and make his exhibit as attractive and useful as possible. At the same time the Exhibition must not lose its collective character.

Each object must be manufactured by the exhibitor, or must be sold under his trade-mark.

Machinery for manufacture of objects for photography, equipments and appurtenances for photographic studios or businesses, and all kinds of frames may be exhibited here.

Trophies at the discretion of the jury.

Class Prizes: Diplomas for gold and silver medals.

### THE ROYAL PHOTOGRAPHIC SOCIETY. ATTENDANCE OF OFFICERS.

The following are the official figures of attendances of officers members of council and committeemen during 1907:—

#### ATTENDANCES OF OFFICERS, MEMBERS OF COUNCIL AND COMMITTEEMEN DURING 1907.

Council Meetings. Number of possible attendances	Committee Meetings. Number of possible attendances	Name.	Number of attendances at

## Photo-Mechanical Notes.

### Photo-Mechanical Processes in Penrose's Annual.

A correspondent writes:—As one interested in process work for my livelihood, I may be allowed to add a few comments to the review of Mr. Gamble's wonderful annual in the "B.J." of December 13. If there is a photo-engraver anywhere who can go without the "Process Year-Book" he must be a funny fish, but there can hardly be many of him about. Photographers, too, may learn a lot as to the facilities at their disposal for the wholesale reproduction of their prints. But to come to my subject:—

There are sixty-eight specimens in colour, thirty-eight in three-colour, nineteen in two-colour, ten in four-colour, and one in six-colour, the last being a photo-lithograph.

There is also this year quite an exceptional list of contributors. Every notable authority upon process work or subjects allied to it appears to be gathered into Mr. Gamble's net. Of the sixty-five articles, no less than nineteen deal with colour-work. Probably the two most important articles in the book are the description of the Omnicolore plate by Alcide Duos du Hauron, and the description of the Warner-Powrie process by Mr. Powrie. He has well illustrated it, and included a very good reproduction of a negative and a positive by three-colour blocks. There is also a reproduction in the book of an Autochrome.

There are no photogravures this year, but three collotypes, one by a Continental firm and two by English firms. The Continental example is certainly far and away ahead of either of the English ones, and should spur our English collotype houses to greater endeavour if they are to equal the work that is being done abroad in this direction.

The chief feature of the whole volume is the attempt to use a paper which should be less uncomfortable than the usual glazed art paper. On the whole the experiment must be counted a success, for although some of the subjects are perhaps a little unsuitable, and appear to bear marks of less careful printing than is required under such exacting conditions, most of them are quite excellent. The half-tones on the text pages are particularly good. No doubt some of the engravers will be upset to think that their work does not show that brilliance and amount of detail that the glazed paper proof showed. Nevertheless, they will be foolish if they do not welcome such an innovation, as nothing has stood so much in the way of further progress of half-tone illustration as the implied necessity to use shiny-surfaced paper, and directly the publishers and public find that they can use something more pleasant there will be a still greater increase in the use of half-tone illustrations.

### FORTHCOMING EXHIBITIONS.

December 31, 1907, to January 4, 1908.—Wishaw Photographic Association. Sec., R. Telfer, 138, Glasgow Road, Wishaw, N.B.

1908.

January 14 to 28.—Glasgow Southern Photographic Association. Entries close January 4. Sec., W. Bryce, 29, Somerville Drive, Mount Florida, Glasgow.

January 30 to February 1.—Nelson Photographic Society. Entries close January 20. Sec., Henry H. Beetham, 98, Brunswick Street, Nelson, Lancs.

February 5 to 7.—Borough of Tynemouth Photographic Society. Entries close January 26. Sec., J. R. Johnston, 29, Drummond Terrace, North Shields.

February 15 to March 7.—Scottish National Salon. Entries close January 20. Sec., Frederick W. Kay, 183, Union Street, Aberdeen.

February 19 to 20.—Royal Albert Institute, Windsor. Entries close February 14. Sec., J. W. Gooch, 9, High Street, Windsor.

February 19 to 21.—Longton and District Photographic Society. Entries close February 8. Sec., T. Mottershead, 32, Stafford Street, Longton.

February 20 to 22.—South Manchester Photographic Society.

- Entries close February 5. Sec., M. W. Thompstone, 2, The Grove, Whitworth Park, Manchester.
- February 23 to March 2.—Birmingham Photographic Society. Entries close February 8. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.
- March 4 to 7.—Ilkeston Arts Club (Photographic Section). Sec., A. Smith, 11, Graham Street, Ilkeston.
- March 7 to 14.—Leicester and Leicestershire Photographic Society. Sec., Lewis Ough, F.C.S., Fernleigh, St. James's Road, Leicester.
- March 7 to 21.—South London Photographic Society. Sec., E. Pady, 260, Southampton Street, Camberwell, S.E.
- March 7 to 12.—Worthing Camera Club. Entries close February 29. Sec., Edmund F. H. Crouch, 11, South Street, Worthing.
- March 12 to 14.—Shropshire Camera Club. Entries close March 2. Sec., W. D. Haydon, The Schools, Shrewsbury.
- March 16 to 19.—Cripplegate Photographic Society. Sec., J. G. Denyer, 15, Ostade Road, Brixton Hill, S.W.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between December 4 and 19:—

- STEREOSCOPIC APPARATUS.—No. 27,331. Applications of stereoscopic vision to optical tubes and camera obscuras. Arthur Bernard Miall, 24, Bournevale Road, Streatham, London.
- SCREEN-PLATES.—No. 27,372. Improvements relating to screen-plates for colour photography. Ilford, Ltd., and Frank Forster Renwick, 8, Quality Court, Chancery Lane, London.
- VIGNETTING.—No. 27,419. Improved vignetting appliance for photographic printing. William Lawrence Parkinson, 15, Water Street, Liverpool.
- CAMERAS.—No. 27,588. Improvements in or connected with photographic cameras. Samuel Lowe, 139, Dale Street, Liverpool.
- MOUNTANT.—No. 27,594. Improved adhesive composition principally intended for use in mounting photographs and the like. George Wilson Morgan, 121, West George Street, Glasgow.
- LENSES.—No. 27,644. Improvements in and relating to objectives or lenses for photographic, stereoscopic and like apparatus. Luiz Auguste Teixeira De Aragao, 11, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

FINDERS.—No. 10,269, 1907. This invention relates to an improved device for finding or gauging the distance of an object for the purpose of photographing it. It refers to that type of distance

finder or gauge in which a plumb indicator is employed to indicate the distance on a scale. Such an indicator can be worked in combination with a view-finder without any sighting or levelling

tube or similar device, and can in consequence be affixed to the side of an ordinary camera or view-finder, and can be used therewith, and the distance for focussing determined while finding the view.

In carrying out the invention there is attached to the camera A on the side, or otherwise adjacent to the view-finder B, or attached to the view-finder B (or in any other suitable position) a plumb or gravity-indicating finger D weighted at  $d$  pivoted on a horizontal pin  $d^1$  with a scale E calibrated and inscribed with feet, yards, and other units of distance. The scale E is placed horizontally or approximately so with the finger D vertical. The

scale is preferably in the same plane as the surface of the view-finder or slightly curved as shown.

The plumb indicating finger D is set in such a position relative to the view-finder or to an index line or point inscribed on the finder that when the ground line of the image is brought to coincide with the edge of the finder or with the index line or point thereon the pointer of the plumb indicator or finger indicates on the scale the distance of the object away.

By recording on the scale the amount of tilt given to the camera the meter can be utilised to indicate the amount of swing back necessary to preserve the perpendicularity of vertical lines in architectural subjects. This can be carried out by engraving or fixing a double scale. The Thornton-Pickard Manufacturing Co., Ltd., Altrincham, and William Booth, 160, Church Street, Eccles.

PHOTOMETERS.—No. 19,768, 1907. The invention relates to means for rapidly indicating the intensity of light, especially for the purpose of determining the required time of exposure of a photographic plate or film. In the present invention use is made of the well-known fact that the diameter of the pupil of the human eye rapidly changes according to the intensity of the light.

In the drawing are shown two forms of apparatus embodying the invention. Fig. 1 is a perspective view of one form of

Fig. 1.

Fig. 2.

apparatus, and Fig. 2 is a section through another form of apparatus.

A is a mirror and B a lens, preferably a plano-convex lens, having its plane face turned upwards. On the upper face of the lens a scale C is marked on the glass. The mirror and the lens are mounted in the two parallel plates of a folding frame D, as shown in Fig. 1. When in use the eye is held close to the lens B and the enlarged image of the pupil and the scale will then be seen in the

mirror, and the diameter of the pupil can thus be directly measured. A table for calculating the time of exposure for a certain sort of plate or other body having a sensitised surface and a certain size of aperture may be attached to the frame.

The device shown in Fig. 2 consists of a box F, which is closed so that no light can enter it except through the eyehole C; closed by a glass plate H, or through the opening E, which may be more or less or wholly closed by means of a diaphragm I (for instance an iris diaphragm). When the device is held tight up to the eye no light can therefore reach the eye as long as the diaphragm I is wholly closed. The pupil will then assume its largest size. On gradually opening the diaphragm I, light will be admitted to the box and the pupil will successively become smaller, and this alteration in size can be observed in the mirror A. On the glass H are provided two marks, and when the pupil is of a diameter equal to the distance between these marks, the size of the opening of the diaphragm will indicate the intensity of the light. As will be seen, this method is an indirect way of measuring the size of the pupil. Haakon Bryhni, Börsen, Drontheim, Norway.

## New Trade Names.

**FEROL.**—No. 297,353. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Charles Francis Dautreband, 117, Pitt Street, Sydney, New South Wales, Australia, manufacturer. October 23, 1907.

**EURYSTIGMAT.**—No. 297,772. Photographic lenses. The London Stereoscopic and Photographic Co., Ltd., 106 and 108, Regent Street, London, W., photographers, photographic apparatus dealers and opticians. November 7, 1907.

## Analecta.

### A New Print Washer.

A writer in the "Photographic News" remarks: Quite a new idea in print washing occurred to me the other day. Filling a large washing-basin with water, I placed the same on a turning-table of a gramophone. I secured to a wooden erection above a flat piece of wood about six inches wide, so that it remained in the water, nearly touching the inside bottom of the basin. After the prints had been put into the water I set the machine in motion, and let it run itself out, the operation taking ten minutes. This I did several times, frequently changing the water. After the first revolution the prints remain against the piece of wood, so that there is a strong current of water rushing about them.

### Gaslight Photography.

I have now used gaslight (says a writer in the "Photographic Monthly") for portraiture, flower and still-life work, interiors, and copying. This last is somewhat more difficult to manage, for a strong top light is a disadvantage, but it is possible to obviate this by placing the object to be copied on steps, or something to raise it sufficiently high to have more front than top light. For portraiture I have found it answer excellently, except from a speed point of view, and this would be more difficult if children were the subjects, so that I would suggest any one wishing to take their portraits should take them while asleep, when, at least, they will not be following an overcrowded path, and many charming pictures should result. In taking adult portraits it is essential to provide the sitter with a comfortable chair, and some provision must be made for a head-rest, as very few people can keep absolutely still for even one minute, and the shortest exposure I have given so far is 1½ minutes. Even if they succeed in keeping still, it is more than likely they would wear rather an agonised expression. By using incandescent gas the exposure can be considerably shortened, particularly if you have at command a light arranged like a billiard-room light, with a large opal shade. With a sitter who has dark hair it is difficult to distinguish the outline of the head when the colour values approximate too closely.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, DECEMBER 27.

Aberdeen Photographic Association. Association Portfolio and Criticism.

MONDAY, DECEMBER 30.

Searborough and District Photographic Society. Photography Prize Slides.

TUESDAY, DECEMBER 31.

Royal Photographic Society. No Meeting.

WEDNESDAY, JANUARY 1.

Borough Polytechnic Photographic Society. "The Camera as a Historian—County Record Work." Frank F. Wood.  
Mill Camera Club. "Autochromes." N. Fearnley.

THURSDAY, JANUARY 2.

Rodley, Farsley and Calverley District Photographic Society. Lantern Evening (Members' Slides).  
Hull Photographic Society. "Practical Re-touching." A. E. Matthews, J. W. Atkinson, and F. Wollons.  
Tunbridge Wells Amateur Photographic Association. "Photography of Marine Life." F. Martin Duncan.  
Balham Camera Club. "Rotary Carbograph Paper."

**SOUTH LONDON PHOTOGRAPHIC SOCIETY.**—At a special general meeting, held on Monday, December 16, at the society's new headquarters, the South London Art Gallery, it was resolved to rescind the resolution to offer bronze plaques only at future exhibitions, which was passed at the last annual general meeting, and to now offer silver as well as bronze plaques in all classes. It is hoped that the awards offered, coupled with the fact that the exhibition will be held in a handsome and spacious Art Gallery, remaining open a fortnight, free of charge; in a densely populated district, will attract a large open entry.

## Commercial & Legal Intelligence.

**RAJAR (1907), LTD.**—Registered December 5: Capital £25,000, in £1 shares. Objects: To adopt an agreement with Rajar, Ltd., H. T. Parke and others, and to carry on the business of manufacturers of and dealers in photographic films, plates, cameras, apparatus, and materials, etc. No initial public issue.

**PHOTOGRAPHIC MATERIALS, LTD.**—The petition of the London Press Exchange, Ltd., for the compulsory winding-up of Photographic Materials, Ltd., was heard in the Chancery Division of the High Court of Justice, before Mr. Justice Parker on Tuesday.

Mr. Gordon Browne, K.C., for the petitioners, who are judgment creditors for £132, said they were supported by other unsecured creditors representing debts to the amount of £231. The Company was formed in 1905 to acquire a business which had been carried on by the Automatic Printing Syndicate, Ltd., and the purchase was effected through a third company, apparently formed for the purpose, and styled "Bertram and Egerton." The consideration was £1,500 in cash and £7,000 in shares. Debentures had been issued at various dates by Photographic Materials, Ltd., as security for debts the company owed—in one case £184 worth of debentures were issued to a creditor three days before the resolution to voluntarily wind up the company was passed. Counsel mentioned that the shareholders complained that the liquidator had sold the business without first consulting them. The petitioners' case was that the transactions relating to the original purchase, and certain dealings of the directors, required investigation.

Mr. Buckmaster, K.C., for the company, pointed out that the petitioner did not suggest that the receiver or liquidator had acted improperly, or that the recent sale of the company had been improperly effected. The petition appeared to have arisen from a feeling of pique that the receiver sold without consulting the creditors. Even assuming that the transaction relating to the issue

of debentures for £184 was a fraudulent preference, the granting of a compulsory order would not help the creditors—it was so long ago the order would not apply.

Mr. Justice Parker said this was one of those cases where it would be of no use to make an order, and therefore the petition failed. The petitioners must pay the costs of the voluntary liquidation.

Mr. Buckmaster: That in form is the costs of the company.

## News and Notes.

MR. TOM REVELEY has purchased the premises and business of Mr. Brewston, of Abingdon-on-Thames, who has occupied the same premises for more than forty years. Mr. Reveley is having the premises rebuilt absolutely, and a new studio of the most modern construction erected. Mr. Reveley believes that it will be as near perfection as possible, with natural backgrounds, such as open fireplace, casement windows, etc. The studio will probably be open soon after Christmas.

ELECTRICAL TRANSMISSION OF PHOTOGRAPHS.—A new method of electrical transmission of photographs, devised by S. Sivelli (writes "Electrical Engineering") is described in an article in "L'Elettricità." The sending apparatus consists of an ordinary photographic camera, in which the sensitive plate is replaced by a plate divided into a large number of small squares, each carrying a selenium cell connected to a constant source of E.M.F. A wire from each cell is taken to a contact-maker, which, when working, makes connection with each circuit in regular order, so that current impulses of varying strengths are sent corresponding to the amount of light falling on the cells. A synchronously moving apparatus forming a part of the receiving instrument causes a sort of pencil to traverse every part of a sheet of paper, and an electro-magnet is provided which causes the pressure of this pencil upon the paper to vary according to the current, so that a heavier line is produced at points corresponding to the selenium cells in the sending apparatus which have not been strongly illuminated.

NOTABLE PORTRAITURE.—MESSRS. Carl Zeiss send us a copy of "Deutsche Kunst und Dekoration," the November issue of which is of very special interest to photographers, as it contains a very fine collection of photographs by Nicola Perscheid, all of which have been produced with Zeiss lenses. The reproductions are excellent and are well worth possessing, while the publication as a whole affords a complete refutation of the idea that high-class anastigmatic lenses are unsuitable for artistic portraiture. Photography is perhaps the only art in which indifferent tools are assumed to be beneficial in the artistic sense. Such an absurd idea would be derided in any other art, and the fact that it is equally ridiculous when applied to photography is fully proved by a study of these productions of Herr Perscheid. The man of genius and ability cannot be provided with too good tools. With indifferent ones he is handicapped, and the results will often show that the tools have exercised more control over the work than the artist himself. Some of the portraits in this book are very striking productions, and a notable instance is the one of Karl Sarnprecht. In this the pose and composition are excellent, while the result conveys the impression that it must be a perfect likeness of the sitter. The portrait of Friedrich Paulsen is another fine example, and so also are those of Fritz Aug. von Kaulbach and Alexander Koch. Messrs. Carl Zeiss, of 29, Margaret Street, Regent Street, inform us that they have only a few copies of this work at their disposal. These, however, they will be pleased to lend to amateur or professional photographers, and we would strongly advise all interested in portraiture to either borrow one for inspection or to call at Margaret Street and see it. The number being very limited Messrs. Zeiss wish all copies to be returned as soon as possible after inspection.

R.P.S. FELLOWSHIP.—At the last Council meeting of the Royal Photographic Society six applications for admission to the Fellowship came before the members, and the following five candidates were admitted:—Mr. George Bankart, a well-known worker and

for many years a contributor to the pages of the "British Journal"; Mr. Henry J. Comley, secretary of the Society of Colour Photographers; Emil Otto Hoppe, an exponent of professional art portraiture in West Kensington; Mr. H. Armytage Sanders, head of the firm of Sanders and Crowhurst; and Mr. J. McIntosh, the hard working secretary of the R.P.S.

THE PHOTOGRAPH CURE.—Whenever an intoxicated man is conveyed to the Denver Police Station his photograph is taken, and the next morning he is shown how he looked the night before. The photograph cure, the police say, is accomplishing wonders.

THE "HOUGHTON" SMOKER.—Last Friday evening the spacious Georgian Hall of the Gaiety Restaurant was filled with the staff of Messrs. Houghtons Limited, and a goodly company it was which cheered to the echo an excellent musical programme provided by Mr. Phil Payne. Mr. Edgar Houghton occupied the chair, and was supported by Mr. George Houghton, Mr. G. A. Spratt, and other directors of Houghtons Limited. Among other prominent members of the wholesale and retail trade present were Messrs. F. Greenwood, H. C. Zerffi, Chas. Zimmermann, Austin Edwards, W. Winter, P. R. Staley, R. J. Kindon, W. A. Furze, J. W. P. Rawlins, W. Lashbrook, T. Foulks Winks, W. Robbins.

Towards the close of the proceedings, Mr. A. Horsley Hinton, in a few appropriate words, congratulated the firm of Houghtons Limited on the success of the function and on the prosperity which it expressed of the well-known British firm. Mr. Edgar Houghton, in responding, spoke of the loyal support which was contributed by every member of the staff. Mr. George Houghton also expressed the pleasure it gave him to meet his friends, old and new, and to watch the continuous progress of the firm with which he had been connected for so many years. A most enjoyable evening came to a conclusion shortly before midnight with vociferations of thanks to Mr. Phil Payne, the entrepreneur of the evening. Among the performers were:—Mr. Mansell Stevens, Miss Carrie Herwin, Miss Rita Bianchi, Miss Ruby Wilson, Miss Marie Schulz, Mr. Randall Jackson, Mr. Percy Watson, Mr. Harry Paul, Mr. Arthur Helmore, Mr. Charles Wreford Graham, Mr. Will Edwards, Mr. Wilson James, Mr. George Blackmore.

CINEMATOGRAPHS NOT A STAGE PLAY.—Although no legal weight can be attached to the incident, a recent ruling of the Lord Chamberlain calls for mention. "Christmastide," which was to have been produced by the New Bioscope Company, by arrangement with Messrs. Jerrard Grant Allen and Jerrold Robertshaw, at the New Theatre, last week, has been banned by the Lord Chamberlain. The performance was to have consisted of three pantomimes in pictures—"The Forty Thieves," "Cinderella," and "Blue Beard"—and a pictorial representation of the origin of Christmas, illustrating the Birth, Childhood, Passion, and Death of Christ. Besides the pictures, "The Fairy Uncle," an adaptation of Tom Gallon's "Christmas Story," and Mr. Barclay Gammon's entertainment were to have been given. But all has now been knocked on the head; there will be no "Christmastide" at the New Theatre. On learning of the Lord Chamberlain's intervention, a representative of the "Pall Mall Gazette" called at the office of the New Bioscope Company to ascertain the reason. "It is because," a representative of the company stated, "the Lord Chamberlain does not consider moving pictures to be a stage play." It was added that it was thought that all difficulty had been overcome by the inclusion in the entertainment of the little play "The Fairy Uncle," that has already been produced at the New Theatre. But the Lord Chamberlain, it seems, is not to be moved from his decision. Whilst the Lord Chamberlain's ban thus prevails in London, it is curious to note that the New Bioscope Company are giving similar entertainments to that proposed for the New Theatre in the provinces. "Indeed," it was stated, "there is a growing demand for pantomimes in pictures. Instead of taking a whole company round for the production, all that is now required is one man with pictures that can be carried in the hand."

A DISPLAY IDEA.—A local dentist—and dentists' cases are much like those of the photographer—has (writes "Camera Craft") a very effective display that gives what seems to be a good idea for the maker of portraits by photography. The entire case is lined with a soft

surface black paper, as is also the front glass, with the exception of an oval opening near the centre. Just back of this opening is supported one of those enlarged models of a tooth about five inches in height, with several gold fillings clearly shown. The effect is very striking, and if the photographer will substitute a neat little medalion in a gold or silver frame the effect would be even better. The general public can be advised that the steal is from the dental profession, and this will, perhaps, stimulate their ingenuity of mind to invent new variations of the alleged dental-chair joke.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### ARTIFICIAL LIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—Mr. G. R. Henderson's letter in your issue of December 6 contains so many misleading statements referring to arc lamps that, as makers of the Jandus photo-lamp, we should be obliged if you would give us space to answer his statements.

The failure of eight arc lamps on Mr. Henderson's visit would be in no way due to the lamps. Even from Mr. Henderson's statement, any electrician would see at once that the trouble was due to the electric fuses, which are used for both mercury-vapour and arc lamps, and a failure of these would have put mercury-vapour lamps out of action for the time being.

Mr. Henderson also implies that no heat appears in using the mercury-vapour lamp. Baron von Hübl, from whom Mr. Henderson quotes, says:—"Compared with the carbon arc the light is weak, and consequently the heat is small, so that the printing-frames can be placed very close." We need hardly point out that if one wishes for still less heat and a still weaker light the familiar candle will answer all requirements, but we hardly think this would be considered by an up-to-date photographer.

Baron von Hübl further says, in page 886 of the "British Journal":—"The disadvantages of the mercury-vapour lamp are its fragility and the impossibility of increasing the illumination—that is, reducing the time of printing by reduction of the distance, as with other arc lamps." The crux of the question lies in the printing time of any given source of light when the frames are placed at a sufficient distance to prevent any bad effects whatever from heat.

We have repeatedly demonstrated the capacity of the Jandus arc in this respect.

With reference to the exposure of six seconds with a stop of  $f/6$  on a special rapid plate, we would refer readers to page 886 of the "British Journal," where Messrs. Houghtons Ltd. illustrate a photograph taken by the Jandus arc lamp, medium size only, special rapid plate, stop  $f/5.6$ , exposure *half to two seconds*. This was taken on an alternating electric circuit, a circuit on which mercury-vapour lamps will not burn at all.

We do not quarrel with the photographer who considers the mercury-vapour nearer to daylight than any other, although he has not yet used an arc lamp. We claim that the Jandus lamp is, for photography, far better than daylight, and we have many letters from actual users that confirm this.

We believe that it is important for the profession to adopt artificial lighting as extensively as possible, so that the public may be impressed with the fact that they can have their photographs taken at any time, and on any day. Postponement of the visit to a photographer on a dull day often means a total loss of the order. We think that the thorough appreciation of the public that their portraits can be taken whenever they wish without the necessity of a previous appointment, will not only result in great benefit to the photographic profession, but incidentally to,—Yours very faithfully,

THE JANDUS ARC LAMP AND ELECTRIC CO., LTD.

A. DENMAN JONES, Works Manager.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

J. Giles, 45, London Road, West Croydon. Photograph of Mr. F. Anson as "The Iron Mask."

INQUIRER.—If your arrangement was in writing, and was stamped at the time with a sixpenny stamp, you can make a pretty good claim for the money; otherwise we do not advise you to take any action.

LONG-FOCUS LENSES.—With regard to the article on page 934 of this week's issue on the use of long-focus lenses in small cameras, will you kindly enlighten me on the following point? In the latter part of this article it is stated that in using a large aperture lens with rather a wide angle, the centre of the plate would be more exposed than the margins. I should like to know if these remarks apply to such a lens when used with the size plate for which it is listed. I ask this, because recently I purchased a lens of an anastigmatic type which has not been long on the market, and the results have not yet been to my satisfaction, but the photographs seem similarly affected, as described in your article. Awaiting the favour of your remarks,—W. J. Howe.

Our remarks apply to all lenses of big aperture that are not specially designed for wide-angle work. To get fairly even illumination the lens should "cover" a very much larger plate than that for which it is listed. Different makers describe the behaviour of their lenses in differing fashions. Some understate the size that it will cover, so as to ensure the lens being used to the best advantage, while others do not take this precaution.

BROKEN NEGATIVES.—A little while ago I sent three half-plate negatives to have enlargements made from them. These came all right, but a few days after the negatives were returned broken in several pieces. I did not take the parcel in myself, and the railway book was signed in the usual way. When I took the box in my hand I heard the broken glass rattling inside, and when I opened it I found, as I expected, the negatives smashed. I immediately wrote to the enlarging people making a claim, which they repudiated, saying the negatives were carefully packed (and they seemed to have been, but the wooden box was broken), and that they were not liable for damage in transit, and that I must claim from the railway company. I have written them, and they reply that as the package was received and signed for, which implied that it was received in good condition, they are not liable, and that as more than a week had elapsed from the time of its receipt they cannot entertain any claim for compensation. How am I to act, as the negatives were valuable ones?—J. B. B.

Under the circumstances we are afraid you will not be able to obtain any compensation for the damage. Most enlargers state on their price lists that they do not hold themselves liable for damage in transit, which relieves them, seeing that the negatives were carefully packed. On the other hand the parcel was received and signed for without comment, which implies

that it was received in good condition. What your representative should have done, seeing that the box was broken, was to have called the carman's attention to it, and opened it in his presence, and then signed the book as received damaged, or not to have received it at all. Then the railway company could not have denied responsibility.

**CONDENSED MOISTURE ON LANTERN SLIDES.**—Whenever I show my slides in the lantern to a few friends, I am always annoyed by their becoming dimmed by moisture settling on the glasses. Sometimes it is on the condensers, sometimes on the slides, and sometimes on both. I do not often notice this in public lantern shows. Will you kindly say how the trouble may be avoided? Thanking you in anticipation.—**GEO. THORNE.**

The trouble may be entirely avoided, or at least greatly mitigated, in this way: Before the display the condensers should be put in front of the fire so that they may gradually become quite warm: that will prevent the moisture condensing upon them when in use. The slides should be dealt with in the same way, and kept warm until they are put into the lantern.

**YELLOW STAINS.**—I printed some three or four dozen postcards with masked borders, intending to use them as Christmas and New Year cards, but they are all more or less stained in yellow patches, like the three I send herewith, and, of course, they are useless. Will you be good enough to inform me, through the "Journal," what is the cause, and how the trouble is to be avoided in the future? I do not think it can be in the fixing, as I used a bath made as follows:—Hypo three ounces, water twenty ounces, and kept them in for eight minutes, and then thoroughly washed for an hour.—**T. PERRY.**

The cause of the stains is not far to seek. It is imperfect fixation. The prints were not kept moving while they were in the fixing solution, consequently it had not free action equally all over. Some were allowed to stick together, as shown by the sharp outline in two of the pictures. The avoidance of the trouble is obvious. We may say that eight minutes' immersion in a solution of the strength mentioned is scarcely sufficient with thick postcards, if many are put in at a time.

**STUDIO QUERY.**—In the spring I propose putting up a studio in my garden for professional purposes. I am a stationer, and intend adding photographs to the business. The studio will be 20ft. by 10ft., and will be 3ft. from the back of the house, being connected by a light covered way. What I want to know is, if the local council can at all interfere with my doing so. I may mention that two or three years ago they did with another person, and made him put up quite a different thing from what he intended to do; but his was on leasehold property, while mine is my own freehold. I shall call the building a conservatory, and that, I fancy, will avoid the building laws. Any advice will be thankfully received.—**BUCKS.**

We do not know the building by-laws of your district, and they vary in different districts. Whether you call your proposed building a conservatory or a photographic studio, it is still the same building, and will come within the same by-laws, whatever they may be. The fact that your premises are freehold while the other man's were leasehold makes no difference. We should say that your best way will be to get out plans of what you propose to do, and then submit them to the local surveyor for his opinion. We may add that a studio of the size you mention is small for professional work.

**POWDERED BITUMEN.**—Will you please tell me if powdered bitumen, as used by photo-engravers, is to be purchased anywhere? I have tried grinding it up in a mortar, but find it very troublesome, as I only want some for experimental purposes—graining copper plates.—**BITUMEN.**

Powdered bitumen, suitable for the purpose, is supplied by Messrs. Penrose and Co., Farringdon Road; also by Mawson and Swan, Soho Square, London, W.

**SPOTTY PRINTS.**—Can you please tell us the cause of the spots on the enclosed prints? We have had several returned by customers like these that have only been done a few weeks. Every care is taken in the washing of the prints, so that cannot be the cause.

We have seen the spots make their appearance after they have only been mounted a week or so. It is only the mounted prints that go in this way. Unmounted ones, done at the same time, show no sign of spots, and for this reason we suspect the mounts to be the cause. We shall be extremely obliged if you will give us your opinion on the subject.—**QUANDARY.**

**T. McLEOD:**—You will find the formulae about which you inquire in the "Almanac," just issued. We cannot afford space to repeat them.

There is very little doubt that the spots are in no way due to the mounts. They are evidently caused by contact with deleterious matters, such as dust, while they are in a wet or moist condition, probably while they are drying after mounting. Most of the spots have a nucleus which can be rubbed off. The dust of photographic work-rooms is usually of a very deleterious nature, being largely composed of particles of hypo, developing agents, and the like. Dust from coke stoves would be likely to produce spots similar to those on the prints sent.

**THE POISONS ACT.**—I am a photographer here, and also work for amateurs, as well as supply them with apparatus and chemicals. Amongst the latter I supply an intensifier, one of which contains bichloride of mercury. I have been told by a chemist here, who also supplies photographic chemicals, that I am liable to a penalty for supplying this one, as I am not a pharmaceutical chemist, and the bichloride of mercury is a scheduled poison, and cannot be sold by me. Will you be good enough to tell me if this is the case, and, if so, whether, if I labelled this solution "Poison," I could still sell it?—**COUNTRY DEALER.**

According to the Poisons Act, no one, except a pharmaceutical chemist, is permitted to sell any of the poisons mentioned in the schedule, and bichloride of mercury is one of them. To label the bottles "Poison" will not exempt you.

**DIRECT CARBON ENLARGEMENTS.**—Will you please tell me if it is possible to make enlargements direct from the negative on ordinary carbon tissue, say, from quarter-plate to 15 x 12? I have one of —'s enlargement lanterns, with oil lamp. I know that is of no use, but a friend will lend me an arc lamp, which I can easily fit to it. What I want to know is, if I fit that and give a fairly long exposure, shall I get a good result? Also, if I sensitise the tissue in a 6 or 7 per cent. solution instead of the usual 3½ per cent. one, will that increase the sensitiveness?—**T. CONNOR.**

If the lamp is a focus-keeping one, so as to keep the arc always in the same position, you can make enlargements, supposing you give sufficient exposure. It will, however, have to be very prolonged. If it is a non-focus-keeping lamp you must not expect to get sharp results, as the point of light will alter its position during the necessarily long exposure. The sensitiveness of the tissue would be increased by using the stronger sensitising solution. If you desire to make carbon enlargements direct, why not use "Carbograph" paper, as described in the "Journal" a few weeks ago? That only requires about the same exposure as bromide paper.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

MENTS of Four Lines (each Line

containing about Seven Words)

of the following Classes ONLY:

Photographers Requiring Assistants  
Operators, &c., Wanting Situations...  
Photographic Promises to be Let or Sold  
Second-hand Photo. Apparatus for Sale  
Miscellaneous Trade Announcements

1/- Each  
Insertion  
Net  
Prepaid.

Each Additional Line, Sixpence.

Those wishing to have their Advertisements addressed to initial letters, c/o BRITISH JOURNAL OFFICE, may do so by remitting 6d. extra per insertion, each advertisement, for receiving and forwarding replies; but no change is made if letters are called for.

**DEPOSIT.**—When dealing with strangers our Deposit System renders the transaction safe, and the commission is trifling compared with the protection thus afforded. The purchase-money must be deposited with the publishers, HENRY GREENWOOD & CO., 24, Wellington Street, Strand, W.C., and all Cheques, Money Orders, &c., made payable to them. Acknowledgment is sent to both parties, and deposit is held until receipt of advice that goods have been received and found satisfactory. In which case the amount deposited is forwarded to the seller, less a commission of 3½ per cent (minimum, one shilling). If goods are not approved the publishers wait original owner's acknowledgment of their sale return before refunding the deposit, the usual commission being deducted. All disputes or questions arising must be settled between the contracting parties.

**SPECIAL NOTICE.**—THE LATEST TIME FOR RECEIVING SMALL ADVERTISEMENTS IS 2 O'CLOCK P.M. ON WEDNESDAYS for insertion in the current week's issue.

LARGE ADVERTISEMENTS should reach the Publishing Office not later than TUESDAY. \* \* \* To prevent delay communications relating to advertisements and general business affairs should be addressed to the publishers, and all advertisements are received subject to their approval or revision, and the right is reserved to refuse any advertisement without giving a reason for so doing.

HENRY GREENWOOD &amp; CO., 24 Wellington Street, Strand, London, W.C.

## This is the HOOD House-mark

It represents the emblem of aspiration—the hope that we may soar with wings of effort to greater heights of excellence in our special paths of Photo-Engraving and Printing.

But just now we seek heartily to thank all those friends, our customers, for the past year's work.

We have really tried to do well for you all, and though things sometimes "get askew" (as they will occasionally, even in the best of places) yet we seem to have pleased most of you, if we are to judge by your many appreciative letters.

Thanks Ladies and Gentlemen, thanks, and

## A MERRY CHRISTMAS TO YOU ALL.

HIGHEST DISCOUNTS TO DEALERS.

*To develop your spools in the Kodak Developing Tank is to guarantee the best possible results from your exposures.*

The Kodak Tank Leaflet gives full particulars.

TO continue to use a dark-room is to continue in a course which involves much discomfort for yourself, and considerable risk of fogging a highly colour-sensitive film without the slightest compensating advantage.

THERE is no necessity to look at your films during development. The best treatment for an over-exposure and for an under exposure is the treatment that is best for a correct exposure, viz., twenty minutes in the Kodak Developing Tank in the developer prescribed.

THE exposed film is transferred from the camera to the Tank in daylight. There it remains for twenty minutes, and the result is a strip of negatives which cannot be surpassed by any other method of treatment.

AND ALL DEALERS.

## 1907-1908.

LOOKING forward into 1908 while the present year is ebbing to its close, the busiest of us may well pause and reflect awhile.

For ourselves—we confess that the number of friends we have made in the passing year encourages us to look forward with confidence to the new. The many expressions of satisfaction with our work, the acknowledgment, in many instances, that our efforts have materially added to the successful carrying out of our customer's plans—all convince us that our policy of "Every print and every enlargement, the best the negative will yield" is the one that will, in 1908 as in the past, best serve to maintain the reputation of the RAINES SERVICE as "The Service that helps."

With the "HELIAR" Lens  
You are Certain of a  
Picture in all Weathers.

The Lens for  
Professional Photographers.

Full  
Aperture  
F4.5.

In  
all  
Sizes.

**THE "HELIAR" LENS.**

The **Heliar**, constructed upon the calculations of Dr. H. Harting, F.R.P.S., is an unsymmetrical lens, the various parts of which cannot be used separately, or in conjunction with the corresponding parts of other focal lengths.

Between two pairs of lenses, consisting each of two lenses cemented together, there stands a single lens, and behind this single lens is placed the diaphragm. Owing to the excellent union of the light rays and the total absence of coma the proportion of aperture up to a focal length of 60 cm. is F4.5, while the field for a plate sharply focussed at full aperture is 48 degrees.

The **Heliar**, when used in conjunction with Voigtländer's Telephoto Attachments, gives excellent results.

A client writes respecting the "Heliar" Lens:—

"Many thanks for your superb catalogue. All that you say in it about your 'Heliar' Lens is perfectly correct—in fact, I find the 'Heliar' to be the best lens I have ever used."

Fully Illustrated Catalogue and "Hints on Lens"  
sent FREE upon application to Readers of this Paper.

## SILENT STUDIO SHUTTER

WORKS IN FRONT OF THE LENS  
OR INSIDE THE CAMERA.

THE MOST PERFECT AND  
SUCCESSFUL STUDIO SHUTTER IN  
THE MARKET. NO VIBRATION.  
PRACTICALLY NOISELESS IN  
WORKING.

A BOON TO THE PROFESSIONAL.  
NO STUDIO SHOULD BE WITHOUT IT.

The special attention of Professional Photographers is directed to this pattern of Shutter as being extremely suitable for Studio Work. It gives exposures of about 1/4th of a second and longer duration.

It is practically noiseless in working, and in consequence the picture is taken without arresting the attention of, or startling the siter, and especially is this the case when the Shutter is used inside the Camera. Many a splendid result is obtained with a minimum of trouble through the agency of the Studio Shutter.

The Shutter is held open for focussing by first squeezing the Ball and then turning the Brass Tan fitted on the rubber tube.

To fit on Lens Hood or  
Tube up to inches  
diameter ... ..

## ISOCHROMATIC SCREENS OR FILTERS FOR INSTANTANEOUS Photography.

Optically perfect. Parallel worked glass from the celebrated  
glass factory of Schott, Jena.

With these screens the exposure is increased only to two or four  
times: they replace the old inefficient screens which required  
from 6 to 20 times exposures.

Sizes:— 3 in. 1 in. 1½ in. 1½ in. 1½ in. 2 in. 2½ in. 2½ in. 3½ in. 4 in.
